IFIP TCS, 2008

Motivations

- n -ary queries $\phi(x_1, \dots, x_n)$ in trees t : select n -tuples of nodes
- fundamental to XML processing tasks
- the set of answers can grow exponentially in $|t|$ ($O(|t|^n)$ in the worst case)
- the answers share common information
- a compact representation is needed

Aggregated Answers (Meuss, Schulz, Bry, ICDT'01)

- join-free term over $\{\times, \vee\}$ and constants $[x \mapsto n]$;

Example (aggregated answers)

XML document

Aggregated Answer

Query: (DVD, Lang, Subtitles)

Advantages of this representation

- efficient model-checking: $\tau \in \text{Ans}(\phi, t)$?
- efficient enumeration: $\tau_1, \dots, \tau_i, \dots$
- advanced query answering:
 - ▶ answer searching, statistics
 - ▶ answer browsing
 - ▶ cascade style query-answering
- view computing

Objective

How compact are aggregated answers? How to measure compactness?

How compact are aggregated answers? How to measure compactness?

- compactness is related to variable independence
- variable independence in the context of infinite constraint databases (Chomicki et. al., PODS'96) (Libkin, TOCL'03)
- only between blocks of variables, and fixed database
- we propose a more general notion: dependency forests
- MSO in ordered finite binary trees

Objective

How compact are aggregated answers? How to measure compactness?

- compactness is related to variable independence
- variable independence in the context of infinite constraint databases (Chomicki et. al., PODS'96) (Libkin, TOCL'03)
- only between blocks of variables, and fixed database
- we propose a more general notion: dependency forests
- MSO in ordered finite binary trees

Question

Given a dependency forest, and a query, are the variables independent w.r.t. this forest?

- 1 **variable independence w.r.t. a partition**
- 2 variable independence w.r.t. a dependency forest

Trees and MSO

- finite ordered **binary** trees t are viewed as structures over the signature $S_1(x, y), S_2(x, y), \text{lab}_a(x), a \in \Sigma$, with domain $\text{nodes}(t)$
- first-order variables x, y, z, \dots denote **nodes**
- second-order variables X, Y, Z, \dots denote **set of nodes**
- existential quantifiers $\exists x, \exists X$, Boolean operators \neg, \vee, \wedge , and membership $x \in X$;
- an MSO formula $\phi(x_1, \dots, x_n)$ defines an n -ary query:

$$\text{Ans}(\phi, t) = \{(u_1, \dots, u_n) \in \text{nodes}(t)^n \mid t \models \phi(u_1, \dots, u_n)\}$$

Trees and MSO

- finite ordered **binary** trees t are viewed as structures over the signature $S_1(x, y), S_2(x, y), \text{lab}_a(x), a \in \Sigma$, with domain $\text{nodes}(t)$
- first-order variables x, y, z, \dots denote **nodes**
- second-order variables X, Y, Z, \dots denote **set of nodes**
- existential quantifiers $\exists x, \exists X$, Boolean operators \neg, \vee, \wedge , and membership $x \in X$;
- an MSO formula $\phi(x_1, \dots, x_n)$ defines an n -ary query:

$$\text{Ans}(\phi, t) = \{(u_1, \dots, u_n) \in \text{nodes}(t)^n \mid t \models \phi(u_1, \dots, u_n)\}$$

Example

Select all the DVDs:

$$\phi(x) = \text{lab}_{DVD}(x)$$

Trees and MSO

- finite ordered **binary** trees t are viewed as structures over the signature $S_1(x, y), S_2(x, y), \text{lab}_a(x), a \in \Sigma$, with domain $\text{nodes}(t)$
- first-order variables x, y, z, \dots denote **nodes**
- second-order variables X, Y, Z, \dots denote **set of nodes**
- existential quantifiers $\exists x, \exists X$, Boolean operators \neg, \vee, \wedge , and membership $x \in X$;
- an MSO formula $\phi(x_1, \dots, x_n)$ defines an n -ary query:

$$\text{Ans}(\phi, t) = \{(u_1, \dots, u_n) \in \text{nodes}(t)^n \mid t \models \phi(u_1, \dots, u_n)\}$$

Example

Select all the triples $(\text{dvd}, \text{lang}, \text{sub})$:

$$\begin{aligned} \phi(x, y, z) = & \text{lab}_{DVD}(x) \wedge \text{lab}_{lang}(y) \wedge \text{lab}_{sub}(z) \wedge \\ & \text{desc}(x, y) \wedge \text{desc}(x, z) \end{aligned}$$

Variable Independence w.r.t. a Partition

- **input:** a formula $\phi(x_1, \dots, x_n)$, a partition $P = \{B_1, \dots, B_k\}$ of $\{x_1, \dots, x_n\}$
- **output:** is ϕ equivalent to a formula of the form:

$$\bigvee_{i=1}^N \phi_i^1(B_1) \wedge \dots \wedge \phi_i^k(B_k)$$

where $\text{freevar}(\phi_i^j) = B_j$. We say that ϕ **conforms** to P .

Theorem

Variable independence w.r.t. a partition is decidable, and a decomposition is computable.

Towards a Characterization of Variable Independence

- For all $i \in \{1, \dots, k\}$, consider:

$$\begin{aligned} \text{Swap}_i(\bar{x}, \bar{y}) &= \forall B_1 \dots \forall B_{i-1} \forall B_{i+1} \dots \forall B_n \\ &\phi(B_1, \dots, B_{i-1}, \bar{x}, B_{i+1}, \dots, B_n) \leftrightarrow \\ &\phi(B_1, \dots, B_{i-1}, \bar{y}, B_{i+1}, \dots, B_n) \end{aligned}$$

Towards a Characterization of Variable Independence

- For all $i \in \{1, \dots, k\}$, consider:

$$\begin{aligned} \text{Swap}_i(\bar{x}, \bar{y}) &= \forall B_1 \dots \forall B_{i-1} \forall B_{i+1} \dots \forall B_n \\ &\quad \phi(B_1, \dots, B_{i-1}, \bar{x}, B_{i+1}, \dots, B_n) \leftrightarrow \\ &\quad \phi(B_1, \dots, B_{i-1}, \bar{y}, B_{i+1}, \dots, B_n) \end{aligned}$$

- intuition: if $t \models \text{Swap}_i(\bar{u}, \bar{v})$ then \bar{u} and \bar{v} are not distinguished by ϕ .

Towards a Characterization of Variable Independence

- For all $i \in \{1, \dots, k\}$, consider:

$$\begin{aligned} \text{Swap}_i(\bar{x}, \bar{y}) &= \forall B_1 \dots \forall B_{i-1} \forall B_{i+1} \dots \forall B_n \\ &\quad \phi(B_1, \dots, B_{i-1}, \bar{x}, B_{i+1}, \dots, B_n) \leftrightarrow \\ &\quad \phi(B_1, \dots, B_{i-1}, \bar{y}, B_{i+1}, \dots, B_n) \end{aligned}$$

- intuition: if $t \models \text{Swap}_i(\bar{u}, \bar{v})$ then \bar{u} and \bar{v} are not distinguished by ϕ .
- Every formula $\text{Swap}_i(\bar{x}, \bar{y})$ defines on a tree t an equivalence relation $\text{Ans}(\text{Swap}_i, t)$ between tuples of size $|B_i|$.

Variable Independence Reduces to Query Boundedness

Theorem

ϕ conforms to $\{B_1, \dots, B_k\}$ iff for all $i = 1, \dots, k$, $Swap_i$ is of bounded index, i.e.:

$$\exists b_i \geq 0, \forall t, |nodes(t)^{B_i}| / |Ans(Swap_i, t)| \leq b_i$$

The decomposition has the following form:

$$\phi(x_1, \dots, x_n) \leftrightarrow \bigvee_j \phi_j \wedge cl_1^j(B_1) \wedge \dots \wedge cl_k^j(B_k)$$

On Deciding Boundedness

Theorem

Given a formula $\phi(x)$, we can decide if there is a bound $b \geq 0$ such that:

$$\forall t, |\text{Ans}(\phi, t)| \leq b$$

Moreover, some bound b is computable.

- 1 translate $\phi(x)$ into a canonical $\{0, 1\}$ -labeling transducer T_ϕ
- 2 decide whether the number of images of any tree by T_ϕ is bounded by some constant [Seidl, habilitation thesis].

Extension to n -ary queries

$\phi(x_1, \dots, x_n)$ is bounded iff for each i , the following is bounded:

$$\text{proj}_i(\mathbf{x}) = \exists x_1 \dots \exists x_{i-1} \exists x_{i+1} \dots \exists x_n \phi(x_1, \dots, x_{i-1}, \mathbf{x}, x_{i+1}, \dots, x_n)$$

Bounded Index Property

Corollary

Bounded index property is decidable for every $Swap_i(\bar{x}, \bar{y})$, moreover, an index is computable.

- 1 define a total order $\bar{x} \leq^n \bar{y}$ on n -tuples of nodes (by an MSO formula);
- 2 decide boundedness of $Min(\bar{x})$, which selects the minimal representatives of the relation defined by $Swap_i(\bar{x}, \bar{y})$.

Orthographic Dimension

Definition (Grumbach, Rigaux, Segoufin, ICDT'99)

Let $\phi(x_1, \dots, x_n)$ be a formula, and \mathcal{P} the set of partitions P such that ϕ conforms to P . The orthographic dimension $d(\phi)$ is defined by:

$$d(\phi) = \min_{\{B_1, \dots, B_k\} \in \mathcal{P}} \max_i |B_i|$$

- how to compute it? try every partition of $\{x_1, \dots, x_n\}$.
- **improvement**: consider only 2-partitions, thanks to the following theorem, adapted from (Cosmadakis, Kuper, Libkin, 01):

Orthographic Dimension

Definition (Grumbach, Rigaux, Segoufin, ICDT'99)

Let $\phi(x_1, \dots, x_n)$ be a formula, and \mathcal{P} the set of partitions P such that ϕ conforms to P . The orthographic dimension $d(\phi)$ is defined by:

$$d(\phi) = \min_{\{B_1, \dots, B_k\} \in \mathcal{P}} \max_i |B_i|$$

- how to compute it? try every partition of $\{x_1, \dots, x_n\}$.
- **improvement:** consider only 2-partitions, thanks to the following theorem, adapted from (Cosmadakis, Kuper, Libkin, 01):

Theorem

If ϕ conforms to P_1 and P_2 , then ϕ conforms to $P_1 \sqcap P_2$.

Relation to answer set representation

We can compute a formula equivalent to $\phi(x_1, \dots, x_n)$ which corresponds to the orthographic dimension, i.e. a formula

$$\bigvee_{i=1}^N \phi_i^1(B_1) \wedge \dots \wedge \phi_i^k(B_k) \quad \text{where } d(\phi) = \max_i |B_i|$$

Relation to answer set representation

We can compute a formula equivalent to $\phi(x_1, \dots, x_n)$ which corresponds to the orthographic dimension, i.e. a formula

$$\bigvee_{i=1}^N \phi_i^1(B_1) \wedge \dots \wedge \phi_i^k(B_k) \quad \text{where } d(\phi) = \max_i |B_i|$$

The aggregated answer on a tree t is of size $O(f(|\phi|) \cdot |t|^{d(\phi)})$.

- compute the answer sets A_i^j of each ϕ_i^j
- represent the answer set by a union (whose size only depends on ϕ , which is fixed) of cartesian products $A_i^1 \times \dots \times A_i^k$.

- 1 variable independence w.r.t. a partition
- 2 **variable independence w.r.t. a dependency forest**

Dependency Forest F

- over a set $V = \{x_1, \dots, x_n\}$ of variables

where $\{B_1, \dots, B_7\}$ partitions V

Conformance to a Dependency Forest F

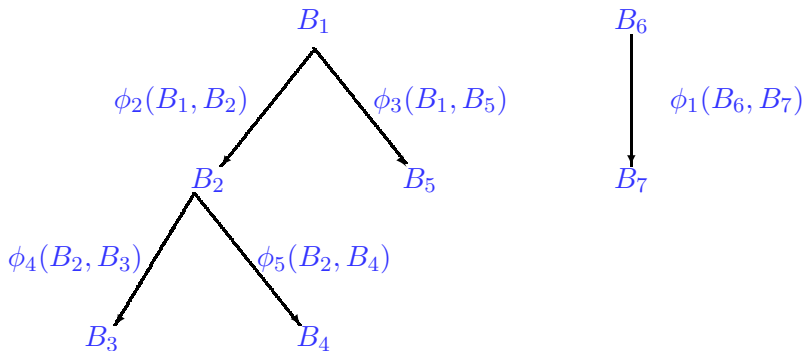

- $\{B_1, \dots, B_7\}$ partitions $V = \{x_1, \dots, x_n\}$

- $\mu : \text{edges}(F) \rightarrow \text{MSO formulas}$
- $\mu(F) = \phi_1(B_6, B_7) \wedge \phi_2(B_1, B_3) \wedge \phi_3(B_1, B_5) \wedge \phi_4(B_2, B_3) \wedge \phi_5(B_2, B_5)$

Conformance to a Dependency Forest F

- $\{B_1, \dots, B_7\}$ partitions $V = \{x_1, \dots, x_n\}$

Definition

A formula $\phi(x_1, \dots, x_n)$ conforms to F if there is a finite sequence μ_1, \dots, μ_k such that $\phi \leftrightarrow \bigvee_i \mu_i(F)$.

Example

The query $\phi(x, y, z) : t \mapsto (DVD, Lang, Sub)$

conforms to

Relation to Answer Set Representation

The set of answers can be represented by an aggregated answer of size $O(f(|\phi|) \cdot |t|^{2b})$, where $b = \max_i |\bar{y}_i|$.

Main Result

Theorem

It is decidable whether a formula $\phi(x_1, \dots, x_n)$ conforms to a dependency forest F .

- 1 decide it for forests of the form $B_1(B_2, B_3) \rightarrow$ signature $\Sigma \times \{0, 1\}^{B_1}$

Main Result

Theorem

It is decidable whether a formula $\phi(x_1, \dots, x_n)$ conforms to a dependency forest F .

- ① decide it for forests of the form $B_1(B_2, B_3) \rightarrow$ signature $\Sigma \times \{0, 1\}^{B_1}$
- ② inductively: if $F = \{T_1, \dots, T_k\}$
 - ▶ decompose ϕ w.r.t. the partition $\{var(T_1), \dots, var(T_k)\}$
 - ▶ get a disjunction of the form $\bigvee_i \alpha_i^1(var(T_1)) \wedge \dots \wedge \alpha_i^k(var(T_k))$
 - ▶ decompose each α_i^j w.r.t. T_j

Main Result

Theorem

It is decidable whether a formula $\phi(x_1, \dots, x_n)$ conforms to a dependency forest F .

- 1 decide it for forests of the form $B_1(B_2, B_3) \rightarrow$ signature $\Sigma \times \{0, 1\}^{B_1}$
- 2 inductively: if $F = B_1(B_2(F_1), F_2)$:

Are tuples of variables really needed in F ?

Proposition

There is an MSO formula ϕ which **does not conform** to any dependency forest whose nodes are labeled by **single variables**.

- take $\phi(x, y, z)$ defined by $lca(x, y) = lca(x, z)$
- find counter-examples for every forest F over $\{x, y, z\}$

- **extend the structures beyond trees**

- ▶ need an MSO-definable total order
- ▶ decidability of boundedness
- ▶ \implies variable independence is decidable for unranked trees

- **extend the structures beyond trees**

- ▶ need an MSO-definable total order
- ▶ decidability of boundedness
- ▶ \implies variable independence is decidable for unranked trees

- **tree pattern queries**

- ▶ n -ary tree patterns with *desc*, *child*, *next – sibling*, *label* tests
- ▶ fragments for which the aggregated answers have size $O(\text{poly}(|\phi|) \cdot |t|)$
