Supplemental Information

The Magnitude of Global

Marine Species Diversity

Ward Appeltans et al.

Supplemental Inventory

Table S1

The proportions of undescribed marine species found for particular taxa and locations. This is related to the main text - section “estimated total global species richness, based on undescribed species in samples collected”.

Supplemental Experimental Procedures

A non-homogeneous renewal process model based on extrapolation of the discovery curve as a logistic function. This is related to the main text section “estimated total global species richness, based on past rates of species descriptions”.

Table S2

Comments on reasoning behind the data on particular taxa in Table 1.

Table S1. The proportions of undescribed marine species found for particular taxa and locations. The total estimated number of undescribed species is ~12,581 (37%) of 33,566 collected (N° of species). This is related to the main text - section “estimated total global species richness, based on undescribed species in samples collected”.

undescribed	N° of species	Taxon	Location	Reference
67%	184	Peracarida	Mid-Atlantic	Grassle & Maciolek [S1]
37%	106	Mollusca	Continental Slope, USA	
64%	367	Polychaeta		
95%	459	Copepoda associated with other species	Madagascar, New Caledonia, Moluccas (note that the Madagascar samples were collected over several years)	Humes [S2]
33%	372	Polychaeta	Georges Bank	Carlton [S3]
71%	158	Polychaeta	Hawaii	
42%	320	Gastropoda	Philippines	
55%	564	Gastropoda	New Guinea	
79%	29	Harpacticoida	Gulf of Mexico	
92%	134	Turbellaria	Great Barrier Reef	
80%	2,000	Mollusca	New Caledonia	Bouchet [S4]
64%	14	Hydrozoa		Koslow <i>et al.</i> [S5]
12-27%	33	Octocorallia		
0-28%	29	Annelida		
43-57%	14	Bryozoa	Seamounts, Tasmania	
30%	10	Mollusca		
35-62%	37	Decapoda		
69-88%	32	Other Crustacea		
4-9%	22	Asteroidea		
8-31%	36	Ophiuroidea		
18-45%	11	Other Echinodermata		
>14%	28	Pisces		
30-40%	>2,000	Nematoda (free-living)	European seas	
ca. 90%	158	Foraminifera		Brandt <i>et al.</i> [S7]
56%	57	Nematoda (free-living)		
70%	100	Ostracoda	Deep regions of the Atlantic sector of the Southern Ocean	
86%	674	Isopoda		
27%	295	Polychaeta		
22%	76	Porifera		
31%	65	Bivalvia		
5%	1,222	Pisces	Tropical eastern Pacific	Zapata & Robertson [S8]
>90%	365	Isopoda	Australia	Poore <i>et al.</i> [S9]
>30%	524	Decapoda	Australia	Poore <i>et al.</i> [S10]
83%	1,409	Turridae (molluscs)	New Caledonia	Bouchet <i>et al.</i> [S11]
61%	79	Tubificidae (oligochaetes)	Western Australia	Erséus ([S12] and references therein)
5-24% (average 14.3)		Azooxanthellate Scleractinia corals	Most of world's oceans.	Cairns [S13]
0-18% (average 6.1)		Zooxanthellate Scleractinia corals	Australia, Caribbean, Japan, Red Sea, Vietnam	
25%	450	Ciliophora (free-living)	Chinese coastal regions of the Bohai Sea and Yellow Sea	Song, Warren, Hu [S14]

64%	14	Rhabdocoel flatworms	Uruguay (July-August 2004)	Van Steenkisten <i>et al.</i> [S15]
61%	71	Rhabdocoel flatworms	Lanzarote (October 2011)	Artois [unpubl. data]
78%	40		Panama (December 2011)	
76%	34	Proseriate flatworms	Lanzarote (October 2011)	Curini-Galletti [unpubl. data]
90%	30		Pacific Panama (December 2011)	
56%	30	Octocorallia	Records of the Western Australian Museum	Alderslade [S16]
60%	50	Octocorallia	New Caledonia and adjacent islands	Grasshoff [S17]
28%	19	Octocorallia	Sinai coast and the Strait of Gubal, Red Sea	Grasshoff [S18]
64%	34	Octocorallia	Indo-Pacific	Van Ofwegen [S19]
40%	15	Octocorallia	Palau, Micronesia	Van Ofwegen [S20]
42%	59	Tubificidae (oligochaetes)	Belize	Erséus [S21]
41%	37	Tubificidae (oligochaetes)	N. T., Australia	Erséus [S22]
41%	41	Tubificidae (oligochaetes)	Western Australia	Erséus [S23]
24%	99	Asciadiacea	Guadeloupe	Monniot [S24-S27], Monniot [S28-S31]
38%	208	Asciadiacea	New Caledonia	Monniot [S32-S37], Monniot [S38-S45]
50%	211	Asciadiacea	Tropical Western Pacific	Monniot [S46], Monniot [S47-S50]
29%	180	Asciadiacea	South Africa	Michaelsen [S51], Millar [S52-53], Monniot <i>et al.</i> [S54]
19%	16	Asciadiacea	California continental shelf	Lambert [S55]
0%	11	Sipuncula	Antarctic Waters	Cutler <i>et al.</i> [S56]
0%	5	Sipuncula	The deep Angola Basin	Saiz Salinas [S57]
40%	10	Pycnogonida	Melanesia	Bamber [S58]
30%	10	Pycnogonida	Taiwan	Bamber [S59]
19%	16	Pycnogonida	Melanesia	Bamber [S60]
23%	13	Pycnogonida	Melanesia	Bamber [S61]
20%	5	Pycnogonida	Ecuador	Bamber & Takahashi [S62]
7%	15	Pycnogonida	W Australia (shallow)	Bamber [S63]
17%	12	Pycnogonida	S Australia	Staples [S64]
15%	13	Pycnogonida	Queensland	Bamber [S65]
17%	6	Pycnogonida	Azores	Bamber & Costa [S66]
14%	50	Pycnogonida	Caribbean Colombia	Muller & Krapp [S67]
24%	17	Pycnogonida	W Australia (deep)	Arango [S68]
7%	204	Ophiuroidea	New Caledonia region	O'Hara & Stöhr [S69], Stöhr [S70]
2%	130	Ophiuroidea	North Atlantic, below 200 m	Martynov & Litvinova [S71]
8%	55	Crinoidea	Bahamas (July 2009)	Messing [unpubl. data]

6%	456	Nematoda	Southern Bight of the North Sea	Vincx [S72]
12%	114	Nematoda	Strait of Magellan and Beagle Channel (South America)	Chen [S73]
27-38%	250-350	Nematoda	Manganese nodule field off Peru, southern part of East Pacific	Bussau [S74]
88%	65	Tanaidacea	SE Australia	Blazewicz-Paszkowycz and Bamber [S75]
92%	26	Tanaidacea	W Australia (shallow)	Bamber [S76]
69%	29	Tanaidacea	Queensland	Bamber [S77]
46%	266	Tanaidacea	Antarctic	Blazewicz-Paszkowycz [unpubl. data]
28%	320	Bryozoa	New Zealand deep sea >500 m (including sea mounts)	Gordon [unpubl. data]
0-100% (average 41.3)	2 to 13	Zoantharia	Galapagos, Singapore, Japan, British Columbia, Cape Verde, Taiwan	Reimer <i>et al.</i> [S78-S87]
92%	26	Leucothoidae (Amphipoda)	Japan	White and Reimer [S88-S90]
24%	17	Echinoidea	North Atlantic	Mortensen [S91-S93]
19%	16	Echinoidea	Gulf of Thailand	Mortensen [S94]
41%	17	Echinoidea	South Atlantic, Antarctic coast & deep water	Mortensen [S92,S95]
29%	14	Echinoidea	Southwest Atlantic coast, Antarctic coast	Mortensen [S92,S96]
29%	14	Echinoidea	Northwestern Australia	Mortensen [S97]
33%	18	Echinoidea	New Zealand & Auckland-Campbell Islands	Mortensen [S98]
22%	144	Echinoidea	Philippines and adjacent regions	Mortensen [S99-S102]
14%	7	Echinoidea	Caribbean deep water	Mironov [S103]
3%	36	Echinoidea	Philippines and Makassar Strait	David & de Ridder [S104]
0%	31	Echinoidea	Antarctic coast, Subantarctic shelf and Kerguelen Islands	de Ridder <i>et al.</i> [S105]
25%	17,135	All taxa	New Zealand	Gordon <i>et al.</i> [S106]
70%	259	Triphoridae (gastropods)	Vanuatu	Albano <i>et al.</i> [S107]

Supplemental Experimental Procedures

There is a large literature on statistical prediction of the number of species remaining to be described [S1–S2], where it is known more generally as the 'number of kinds' problem. Most methods of estimation require data in the form of a sample of individuals of known size, where each individual in the sample has been identified so that the proportional abundance of individuals among species in the sample is known.

Such samples are available for only a small portion of the biosphere, making their use difficult. However, the global rate of species description is known, allowing curve fitting and extrapolation to be used for prediction [S3–S7]. We compared the expert-based estimates on the total number of marine species to predictions generated by a non-homogeneous renewal process model based on extrapolation of the discovery curve as a logistic function. The logistic function has the form

$$\text{Number discovered by year } t = \frac{N}{1 + \exp(-\beta(t - \alpha))},$$

and takes an 'S' shape, going from 0 at $t = -\infty$ to N at $t = +\infty$. The logistic function is a popular choice as a model for the trend in species discovery in a given taxon, as it has the property of an initial slow rate of discovery, rising to a peak before discoveries tail off when most of the species in the taxon are described. The three parameters of the function are N , the total number of species to be discovered; α , the year of maximum rate of discovery; and β that describes the overall rate of discovery, with a larger β implying a faster rate. This has the advantage over other models of producing confidence limits based on the variation in the rate of description between years [S8]. This model is stochastic and describes the time between the discovery of species as a renewal process [S9] where the mean number discovered as a function of time follows a logistic function. Bayesian statistical inference methods are used to fit the discovery curve to this model, giving an estimate of the 3 parameters of the logistic function and in particular an estimate of N , the total number of species. This is then used to estimate the number of species in the taxon remaining to be described.

Unfortunately, predictions based on extrapolating a logistic curve are very sensitive to the fitted value of α , the date of maximum rate of discovery. That date is very difficult to estimate from the data in cases where there is no sign that it has been reached (*e.g.*, groups where the majority of species remain to be described), making the application of this model challenging. In these cases, it is only assumed that the date of maximum rate of discovery occurs between 2010 and 2450. In our analysis we focused on lower and upper bounds for the predicted numbers of species.

Table S2. Comments on reasoning behind the data on particular taxa in Table 1.

<p>Chlorophyta, Rhodophyta, Cryptophyta, Haptophyta, Phaeophyceae, Bacillariophyceae, Chrysophyceae, Euglenozoa [Michael D. Guiry, Olivier De Clerck]</p>	<p>Described + nominal Data on described species and the percentage of synonyms are based on AlgaeBase (Guiry & Guiry, 2012).</p> <p>Undiscovered Several papers have previously addressed algal diversity and provided detailed estimates on the number of species, known and unknown, for various algal groups (<i>e.g.</i>, Andersen, 1992; John, 1994; Norton <i>et al.</i>, 1996; John & Maggs, 1997; Adl <i>et al.</i>, 2007). The numbers presented in these papers are the result of censusing taxonomic experts for specific groups. The total number of recognized species ranged from approximately 29.000 (Adl <i>et al.</i>, 2007; lower estimate) to 43.400 (Andersen 1992; upper estimates). Even though on average estimates of global diversity were about 2-fold higher than the currently recognized number of species, the estimates differed widely among studies and groups. Most notably, estimates of diatom richness ranged from 100.000 species to 10 million, which would indicate that 90–99% of diatom species remains unknown to date. But estimates for other groups also display large variation. The Eustigmatophyceae for example, were considered to comprise between 1000 and 10.000 species by Andersen (1992) and John (1994), while Adl <i>et al.</i> (2007) go for a more modest global estimate of 30 species. Important, the abovementioned studies address global algal diversity and hence the numbers presented refer to the combined marine, freshwater and subaerial diversity. The percentage of marine species differs widely among groups. Whereas the Chlorarachniophyta, Dinophyta, Haptophyta, Rhodophyta and Phaeophyceae are predominantly to exclusively marine, other groups are much more speciose in freshwater habitats (<i>e.g.</i>, Chlorophyta, Chrysophyceae and Euglenozoa) (Dring, 1982; Van Den Hoek <i>et al.</i>, 1995; Edvardsen & Medlin, 2007; Ishida <i>et al.</i>, 2007; Moestrup & Daugbjerg, 2007). The Diatoms are predominantly marine or marine/brackish (63%) (Mann, 1996), but about 25% is exclusively restricted to freshwater habitats. These differing ecologies among groups make it difficult to tease out the marine components and complicate comparison of algal species richness. The estimates of unknown diversity are those presented by Adl <i>et al.</i> (2007), except for Chlorophyta and Bacillariophyceae. Numbers have been adjusted for the fraction of marine taxa. These numbers are rough estimates that depend critically on the estimates of total richness, the percentage of marine taxa and equal taxonomic effort in freshwater and marine environments. For two groups of algae, Chlorophyta and Bacillariophyceae, extrapolation of the data by Adl <i>et al.</i> (2007) yielded unrealistically high species numbers that await description. Estimates of $1-2 \times 10^5$ Chlorophyta, 13.8% of which is marine (Dring, 1982), are probably overly enthusiastic. We estimate a maximum of 2,500 marine Chlorophyta, 1,200 of which remaining to be described. Likewise, an estimate of 2×10^5 Bacillariophyceae (Mann, 1999; Adl <i>et al.</i>, 2007) with 63% of the genera being marine (Mann, 1996), would leave more than 1.2×10^5 marine species to be described. We concur with Mann (1999) in that there are indeed a lot of diatom species, but extrapolation of freshwater diversity patterns to the marine environment, is likely to overestimate the marine diversity. A maximum of 50,000 is therefore suggested.</p> <p>Cryptic</p>
---	--

With the notable exception of Adl *et al.* (2007), estimates of algal diversity largely predate the wide-scale application of molecular sequence in phycology. Sequencing of target genes in individual organisms or more recently by environmental sequencing has revolutionized algal systematics at every taxonomic level. At lower taxonomic levels, gene sequences have confronted phycologists with the notion that algal genetic diversity is in many cases inadequately reflected by the morphology of the organisms. This mismatch between genetic diversity and morphology has been the focus of a whole body of research over the past two decades. Regardless of the taxonomic group, adequately sampled datasets nearly always reveal a plethora of cryptic or in some cases pseudocryptic species. (Lajeunesse, 2002; Montresor *et al.*, 2003; Saez *et al.*, 2003; De Clerck *et al.*, 2005; Saez & Lozano, 2005; Sarno *et al.*, 2005; Saunders & Lehmkuhl, 2005; Evans *et al.*, 2007; Lilly *et al.*, 2007; Medlin *et al.*, 2007; Kooistra *et al.*, 2008; Leliaert *et al.*, 2009; Verbruggen *et al.*, 2009; Boo *et al.*, 2010; Gomez *et al.*, 2011; Piganeau *et al.*, 2011).

Undescribed, collected

The main challenges, however, nowadays are not set by disclosing diversity, but consist of linking genetic diversity to names in the literature and ultimately to the specimens housed in herbaria. The ‘low morphology’ problem (Vanoppen *et al.*, 1993) of single-celled photosynthetic eukaryotes and seaweeds does not only complicate diversity assessments of living organisms, it also makes accurate interpretation of type material and historical collections a daunting task. With our current knowledge it is therefore nearly impossible to predict how many species have been collected but await formal description. The numbers of Bebbler *et al.* (2010), predicting that more than half of the undescribed flowering plant species has been discovered and stored in herbaria already, probably hold up for algae as well. If one interprets ‘discovered’ as being recognized as undescribed, this number is probably very low.

<p>Mangroves [Farid Dahdouh Guebas, Koedam Nico]</p>	<p>Described + Nominal It is important to highlight that the list of Mangrove associates is never-ending and if one refers to mangroves one should consider only the species that are either Minor or Major mangrove components. Some people who live in one part of the world argue that in their part of the world mangrove-associate or even terrestrial trees are considered mangroves, but this lead to absurd situations in which the number of mangroves “explode” at the expense of the management of true mangroves (minor + major).</p> <p>Undescribed, collected My best guestimate is that there are none, or at least they might be the same as the ones under undiscovered.</p> <p>Undiscovered My best guestimate is that in countries where congeneric species are present, there might be undiscovered hybrids. An analysis on the geographic data in the Mangrove Reference Database and Herbarium (Massó i Alemán et al, 2010) leads to the guestimate of the theoretical hybrids below. This means that the putative parents occur in the same country and may therefore have crossed. However there are 3 caveats, 2 of which I can resolve if the resolution of the other marine species that you are investigating is higher and if I have more time: (1) I did not take into account country size (more likely to have undiscovered species or hybrids in large countries with large mangrove areas), and (2) co-occurrence in a country does not necessarily</p>

	<p>imply co-occurrence in the same forest.</p> <p>Guestimate of number of totally new species : 0–5</p> <p>Potential undiscovered hybrids : 54 hybrids, being Between <i>Acanthus ebracteatus</i>, <i>A. ilicifolius</i> and <i>A. xiamenensis</i> : 3 hybrids Between <i>Acanthus ilicifolius</i> and <i>A. volubilis</i> : 1 hybrid Between <i>Acrostichum aureum</i>, <i>A. danaeifolium</i> and <i>A. speciosum</i> : 3 hybrids Between <i>Aegiceras corniculatum</i> and <i>A. floridum</i> : 1 hybrid Between <i>Avicennia integra</i> and <i>A. marina</i> : 1 hybrid Between <i>Avicennia alba</i>, <i>A. marina</i>, <i>A. officinalis</i> and <i>A. rumphiana</i> : 6 hybrids Between <i>Avicennia germinans</i> and <i>A. schaueriana</i> : 1 hybrid Between <i>Bruguiera hainesii</i> on one hand and <i>B. cylindrica</i>, <i>B. gymnorrhiza</i>, <i>B. parviflora</i> or <i>B. sexangula</i> on the other : 4 hybrids Between <i>Bruguiera cylindrica</i>, <i>B. exaristata</i>, <i>B. gymnorrhiza</i>, <i>B. parviflora</i> and <i>B. sexangula</i> : 9 hybrids (excl. the ones documented already) Between <i>Camptostemon philippinense</i> and <i>C. schultzei</i> : 1 hybrid Between <i>Ceriops australis</i>, <i>C. decandra</i> and <i>C. tagal</i> : 3 hybrids Between <i>Excoecaria agallocha</i> and <i>E. indica</i> : 1 hybrid Between <i>Heritiera fomes</i>, <i>H. kanikensis</i> and <i>H. littoralis</i> : 3 hybrids Between <i>Heritiera globosa</i> and <i>H. littoralis</i> : 1 hybrid Between <i>Kandelia candel</i> and <i>K. obovata</i> : 1 hybrid Between <i>Rhizophora stylosa</i> on one hand and <i>R. mucronata</i> or <i>R. samoensis</i> on the other hand : 2 hybrids Between <i>Sonneratia hainanensis</i> on one hand and <i>S. alba</i>, <i>S. caseolaris</i> or <i>S. ovata</i> on the other hand : 3 hybrids Between <i>Sonneratia alba</i>, <i>S. apetala</i>, <i>S. caseolaris</i> and <i>S. griffithii</i> : 5 hybrids (excl. the ones documented already) Between <i>Sonneratia alba</i>, <i>S. caseolaris</i>, <i>S. lanceolata</i> and <i>S. ovata</i> : 3 hybrids (excl. the ones documented already) Between <i>Xylocarpus granatum</i> on one hand, and <i>X. mekongensis</i> or <i>X. moluccensis</i> : 2 hybrids</p> <p>The 3rd caveat is related to the question: if these hybrids exist wouldn't someone have noticed it by now in these well-populated coastal ecosystems? Is this theoretical analysis, even though based on occurrence data, not an overestimation? I believe it is, and if based on discovery of hybrids over the last 20 years I tend to say the guestimate should be closer to 5–10 than to 50!</p> <p>References Massó i Alemán, S., Bourgeois, C., Appeltans, W., Vanhoorne, B., De Hauwere, N., Stoffelen, P., Heughebaert, A., and Dahdouh-Guebas, F. (2010). The 'Mangrove Reference Database and Herbarium' Plant Ecol. Evol. <i>143</i>, 225–232.</p>
Ciliophora [Alan Warren]	<p>I made estimates based on the arguments proposed by Finlay <i>et al.</i> (1996, 1998) and Foissner <i>et al.</i> (2008), and following extensive discussions with Genoveva Esteban (co-author of Finlay <i>et al.</i>, 1996, 1998).</p> <p>Undiscovered This, of course, is highly debatable, and especially difficult to estimate for parasitic or commensal forms as we know little about their host species</p>

specificity. Basically, the number of undiscovered species of such forms may depend on the number of unknown host species.

The 'moderate endemicity' model (Foissner et al, 2008) states that the total number of ciliate species is significantly underestimated largely due to: (1) undersampling; (2) previously unrecognised morphological variation, and; (3) the existence of sibling species, a lack of understanding of the genetic species diversity, etc. When these factors are taken into account it is estimated that 83 – 89% of free-living ciliate diversity remains undiscovered (Foissner et al., 2008).

Maximum bounds: (1) Habitat studies (undersampling) suggests that the number of species should be doubled: using the upper limit of described species (2,421) gives a revised total of 4,842. Using the lower limit (2,115) gives a revised total of 4,230.

(2) Unrecognised morphological variation suggests that this figure should increase by a further 50%. Based on the upper limit value (4,842), the number should be increased by 2,421 giving a further revised total of 7,263. Based on the lower limit value (4,230) the number should increase by 2,115 giving a further revised total of 6,345.

Minimum bounds: According to Esteban (pers. comm.) a 50% synonymy rate should be applied to the total estimated (morpho)species diversity. Thus for the lower limit value (6,345), a 50% synonymy rate results in 3,173 (morpho)species.

Thus, the maximum and minimum bounds for the estimated total numbers of marine ciliate (morpho)species are: maximum 7,263; minimum 3,173.

Cryptic

According Foissner *et al.* (2008), genetic and molecular evidence suggests that the ciliate (morpho)species diversity must be doubled or trebled.

Maximum bounds: Trebling the maximum number of (morpho)species (7,263) gives 21,789. Thus, if the number of (morpho)species is 7,263 then the number of cryptic molecular species is 14,526. Adding these together gives a maximum total of 21,789 marine ciliate species.

Minimum bounds: According to Foissner et al.'s (2008) lower estimate, the number of cryptic molecular species is the same as the number of (morpho)species, *i.e.*, the latter value must be doubled to give the total species number. Thus, the number of (morpho)species (before applying the 50% synonymy rate) is 6,345. Doubling this gives 12,690. However, according to Esteban (pers. comm.) a 50% synonymy rate should also apply to the number of cryptic molecular species. Thus of the 12,690 cryptic species, 6,345 are redundant. Subtracting this from the 12,690 cryptic species gives a total of 6,345 marine ciliate species.

Therefore, the maximum and minimum bounds for the estimated total numbers of marine ciliate species are: maximum 21,789; minimum 6,345.

Note, all this assumes that the estimates derived for free-living species also apply to non-free-living species.

<p>Foraminifera [Bruce Hayward]</p>	<p>Described We have Ellis and Messina catalogue of published foram species and descriptions. There are nearly 50,000 species described and named — but that includes a majority from the fossil record. Species described from the modern are not separated out and many species described from the fossil are still extant.</p> <p>John Murray (2007) recently published an estimate based on the data he assembled world-wide for his book. However, I have little faith in his methodology or assumptions. His initial number is based on specimens recorded stained (ie contained protoplasm) in studies. Fewer than 20% of studies on modern forams have stained their specimens in processing. As a result fewer than 50% of the species recorded from NZ for example are in his count and even lower percentage from the deep sea. I disagree with him that only 50% have been described - I think the number is a lot higher, except for cryptic taxa that can only be identified by molecular studies. I also think far greater percentage is cosmopolitan but this is obscured by multiple descriptions and namings from different regions. I think around 5,000 species is reasonable, which is not far off Murray's maximum.</p> <p>Only one small family is complete — one that I monographed 20 years ago and no new species have been found since then, even in the fossil record.</p> <p>Clearly we will never have a precise answer to your questions but even a near accurate estimate is still some time (years?) away.</p> <p>Nominal Would be >10,000</p> <p>Undescribed, collected Might be <1000</p> <p>Undiscovered If molecular species are excluded then <500. I will watch these numbers change over time.</p> <p>References Ellis and Messina catalogues, New York: Micropaleontology Press, AMNH. Available from http://www.micropress.org/e_m.html</p>
<p>Radiozoa (polycystine) [David Lazarus]</p>	<p>Described + Nominal There are a total of ca 570 polycystine radiolarian species names collated from the plankton literature of the last ca 30 years by various people, including Demetrio Boltovskoy and Kozo Takahashi, the list provided by EOL to Jane Dolven, Annika Sanfilippo and myself, and additions by other contributors. Of these, 400 are considered by us to be valid, 160 are thought</p>

	<p>to be synonyms, and around 10 have not been resolved yet. This implies a synonym percentage of 29%. Note that we are explicitly excluding the many hundreds, probably >1,000, additional names for presumed living polycystine species introduced in the 19th century but not used in any of the modern literature sources. Most of these early names are either clearly artificially split species or nomen dubia, having minimal description, no illustration, and no type material. Many of these early names may not even be really from the plankton but from sub-fossil material (<i>e.g.</i>, up to a few thousand years old) present in the surface sediments, or even older fossil material reworked into younger layers. Please also note that we are discussing only the polycystine radiolarians. There are two other groups often referred to as 'radiolaria' — the Phaeodarians and the Acantharia. We do not have any useful summary data on diversity yet for either of these groups, though neither group is as diverse as the polycystines.</p> <p>Undiscovered Although I do not work with the plankton directly myself, only with the surface sediments, I can confirm the comment made earlier by Kozo. It is highly unlikely that there are more than ca 10% truly 'undiscovered' (<i>i.e.</i>, unsampled) living polycystine taxa — plankton provinces are large and have been sampled repeatedly by many workers, both directly in the water column and even more intensively from surface sediments.</p> <p>Cryptic What is still largely unknown is how many cryptic species there are. This is a major problem for protists. All genetic studies so far find very high levels of cryptic or pseudo-cryptic species. The number of biological species, to the extent this concept applies in protists, may be much higher than the morpho-species count — possibly twice as much and protists diversity may grow significantly in the future, not from unsampled material but by refined (genetic) character analyses.</p> <p>Based on rates of cryptic diversity seen in sister groups, <i>e.g.</i>, planktonic foraminifera, coccolithophores, total species diversity for radiozoa might be 500-1,500.</p>
Fungi [Paul Kirk]	<p>Described From the recently published Marine Fungi (E.B.G. Jones) there are 1,035 'obligately' marine species — by this I mean they occur in marine environments by 'choice' rather than by accident ... they are not 'contaminants'.</p> <p>Nominal Add heterotypic names and that figure rises to 1,156.</p> <p>Undescribed, collected I guess there are about 200 undescribed species from collection based on an estimate of the collecting activity and the number of new species described in recent years. There may be more than this from environmental sampling but this is an area where I have no information as little has been published.</p> <p>Undiscovered If we assume that there are a global total of 1.5 million fungi and we currently know 100,000 then we can apply the same ratio to marine fungi and arrive at an estimate of $1,000 \times 15 = 15,000$.</p>

<p>Acanthocephala [David Gibson]</p>	<p>The number of undescribed and undiscovered species are complete guesstimates.</p> <p>Cryptic There is genetic evidence, as far as I am aware, from only one 'species'. My estimates range from 50–150.</p>
<p>Polychaeta [Geoffrey B. Read.]</p>	<p>Described and Nominal 12,632 accepted (includes 659 unchecked, 259 yet to be entered in WoRMS), and 6696 unaccepted, including 9 homonyms, plus (another category outside 'unaccepted') 122 Nomen dubium, 13 Nomen nudum, thus a total number of nominal species of 19,463.</p> <p>Since 1758, the beginning year of Linnaean nomenclature, the current total of nominal species (about 19,500) has accumulated at a modest overall average of around 90 Polychaeta described per year, with the number varying from fewer than 5 (mostly back in the 18th century) to a startling peak of 685 per year (in 1866). We would hope for an increasing pace in modern times with steadily more taxonomists interested in the group and working, but as yet this trend is not pronounced. WoRMS data shows that for the last 50 year period with full figures, 1956 to 2006, the average has been 130 per year, with the most species described in this period of 248 in 1972. The most productive years for polychaete taxonomy were back in the era 1860–1880 which contained four years with over 300 species described per year. This is because major monographs by Quatrefages, Kinberg, Schmarda, etc, were published during that time.</p> <p>Undescribed, collected Glasby <i>et al.</i> (2009) reported 34 % known undescribed species documented in collections for New Zealand seas in 2000, the year of their assessment, and estimated the likely number of species was double the then total of 763. Since most of the world apart from well-explored coasts such as along the northwestern Mediterranean and North Sea, are probably less or equivalently explored for Polychaeta as New Zealand, it seems conservative to extrapolate that 80 % of worms in collections worldwide are described, making a world total undescribed in collections of an additional 3,158 species. New Zealand museums are expected to have a somewhat higher number of undescribed species than elsewhere (large offshore collections in New Zealand have not been described). A further conservative extrapolation merely doubling the total described and known undescribed gives about a world fauna of around 19,000 (18,948) Polychaeta species, but a total of 25,000 to 30,000 species would not be surprising.</p> <p>Cryptic Based on the experience in recent papers there would be between >1 to >5 molecular cryptics for every valid name, conservatively (one paper found 10), with mostly towards the lower limit applying. As usual the Polychaeta are so disparate that the proportion is likely to fluctuate wildly between families, and there simply has not been sufficient of this work done to assess the situation overall, so a more precise estimate is not possible. Noting that people tend to look for cryptics when they're already suspicious.</p> <p>Reference: Glasby, C.J., Read, G.B., <i>et al.</i> (2009). Phylum Annelida. Bristleworms,</p>

	<p>Earthworms, Leeches. In Gordon, D.P. (ed.) The New Zealand Inventory of Biodiversity: Volume 1. Kingdom Animalia: Radiata, Lophotrochozoa, and Deuterostomia. Christchurch, New Zealand. Canterbury University Press. p. 312–358.</p>
<p>Hirudinea [Jürgen B. Kolb]</p>	<p>Described and nominal The list of names as of today stands at nominal 249 and discounting synonyms at 179 valid species.</p> <p>Undescribed, collected Chances are slim to find many marine fish leech specimens in existing collections as the conventional sampling techniques leading to their existence make it nearly impossible to catch these parasites before they detach and fall off their hosts. Leeches tend to be lost off their hosts while trawling, bringing the sampling equipment to surface or on board during the subsequent handling of material. Furthermore, there is often very little time during an expedition to look at a greater number of fish host individuals, including inspection of the gill chambers, or even other temporary hosts to find the often small and inconspicuous animals. Nevertheless, sometimes leech specimens are found alongside their carrier species upon close inspection. Thus I assume a potential of 15-35 yet to be described species lie hidden in the collections around the world.</p> <p>Undiscovered The leech species living in the marine environment are elusive parasites and are very difficult to study, thus, our knowledge to their true number is very limited. In particular rough seas such as the North Atlantic and the polar regions are under-sampled due to logistical but also financial constraints. This in combination with the parasitic life strategy leads to a low success rate in discoveries and inevitably limits our knowledge of the true marine leech fauna. If one considers that only a handful of experts work on the taxonomic field of marine leeches, it is remarkable that particularly in coastal habitats there are still new species discovered with a reasonable frequency of only a few years apart. I hold at least one new species from Antarctic waters in my collection for future description. The actual number of species in the marine world could well be much greater than currently known. I therefore propose to expect a range for undiscovered morphospecies of 50-100.</p> <p>Cryptic As of today, unfortunately an estimate to the total number of cryptic species has to be an educated guess rather than based on facts as we simply lack the necessary data. The new genomic era changes this in the near future with information becoming available now from bar coding as well as whole genome sequencing projects. Assuming vast similarities in evolutionary terms for marine invertebrates on a global scale and thus genetic diversity, as far stretched as this might be, I propose adopting the generally accepted 10% margin of the known morphospecies to be cryptic. Thus, considering the severe data deficiencies for most marine habitats, I would not be surprised if future molecular work discovers 5-20 or more cryptic piscicolid species.</p>
<p>Oligochaeta [Christer Erséus]</p>	<p>Described The 910 currently known marine morphospecies are still a valid number, as compiled by Tarmo Timm in 2009; virtually nothing has been added since</p>

	<p>then. [I spend most of my time on molecular systematics these days, and never seem to get around describing all the undescribed marine worms I have.]</p> <p>Undescribed, collected My previous estimation of (roughly) 300 undescribed species (those present in my own collections) is up to date too, as I have not collected anything really new during the last 1–2 years.</p> <p>Undiscovered Based on a gut feeling, we probably have just described about a tenth of all species out there. Virtually nothing is known from the South American and African coasts, and large parts of the Polar regions, Asia and the Indo-Pacific Islands. Not to mention the deep sea, from where we only have scattered records; these latter records, however, indicate a rather high diversity). If you ask for a 95% interval, it would be between 5,000 and 15,000.</p> <p>Cryptic Although I am finding cryptic species all the time, it is extremely difficult to translate this into a general percentage (or a similar measure). Today I concentrate my research on non-marine oligochaetes, and there are probably (and totally) hundreds of cryptic species among all common freshwater and terrestrial morphospecies, including the “cosmopolitan” taxa that are so popular as model organisms in research around the world. For marine worms, I have preliminary genetic evidence of cryptic speciation in at least 15 morphospecies, which is a low percentage of the about 300 marine species that I have sampled for DNA so far. Then it should be noted, however, that for the majority of my many marine species, I have sampled only one specimen or population, and I am sure that the number of sibling species will increase with wider geographical sampling. What I dare to hypothesize is that at least 10% of all marine oligochaete morphospecies known today are each containing 2 (or in many cases >2) cryptic species. Thus 10% of total morphospecies (6,000–16,000) contains at least one extra, cryptic species = >600–1,600.</p>
<p>Acarina [Ilse Bartsch]</p>	<p>Described Acarina: known species (end of 2010)</p> <ul style="list-style-type: none"> • Prostigmata: Halacaridae 1098 marine species (1122 valid species minus ca 25 exclusively freshwater species) • Prostigmata: Pontarachnidae 42 species • Astigmata: Hyadesiidae 48 species • Oribatida: Ameronothroidea 30 species • Not included are species of a group called Mesostigmata; I would say, they are terrestrial rather than aquatic. <p>The sum of that, 1218 valid species. This is the number of momentarily valid species, synonyms are ignored</p> <p>Undescribed, collected About 100 new (undescribed) species are hanging around in collections.</p> <p>Undiscovered In recent years, I received material from parts of the world not studied before, the result; more species than described as new ones have been</p>

	<p>withdrawn and, also surprisingly, most of the species were known from localities far away. I expect the number of undiscovered species (on the basis of morphological characters) between 1X and 1.5X that already known, accordingly between 1320–1980 species. If you exclude the 100 species in collections it would be 1220–1830 species.</p> <p>Cryptic There are some few very widespread species, widespread mainly in a biogeographical but also ecological sense and range. One may expect the one or other cryptic species amongst these species. A lot of species are known from a single locality/sample. Less than 10 % of presently described species may not be just one but two (or more) species, though actually, there is not a single record of a cryptic species. I think there aren't many cryptic species amongst the halacarid mites. Just to give a number, 3–8 % of the described species may prove to represent a cluster of species, in all perhaps 150, max 200 new species.</p>
<p>Merostomata [Geoff Boxshall]</p>	<p>Described and nominal There are 4 valid species but I have seen several other invalid names at various times. The only uncertainty is about synonyms.</p> <p>Undescribed and undiscovered One species awaiting description; no unknown new species predicted, although it is always possible that molecular techniques might reveal cryptic species.</p>
<p>Pycnogonida [Roger Bamber]</p>	<p>Decribed 1307 species.</p> <p>Nominal 1348 species names.</p> <p>Undescribed, collected 150–500. Based on looking at material awaiting study in Museums in London, Cape Town, Wellington (NZ) and Melbourne. Then multiplying by number of Museums likely to have some material (only one museum currently has an in-house pycnogonid researcher), error margins (max min) based on estimated disparity between those four collections.</p> <p>Undiscovered 979–1650. The minimum number is based on analyzing the number of new species described per year over the last 20 years for 10 sea regions where there has been study in the last 20 years (surprisingly consistent), and assuming the same value for the other regions (where there has not been study in the last 20 years), and extrapolating for the number to be found over the next 60 years in the best studied areas (about 130 years of proper study), and allowing for the fact that those less-well-studied regions have more species awaiting to be described by assuming a similar accretion rate had they also been studied already for 130 years. [Annual “accretion” curve of new species over the last 20 years does not asymptote, so this may be an underestimate!]</p> <p>Cryptic 50–100. Based on an estimate of the number of species currently far-too-widely “distributed” for a taxon with no dispersive phase, together with the</p>

	<p>number of new taxa confirmed by molecular means from the few recent studies on such “widespread” species, with “range” generated by allowance for number of recent synonymies.</p>
<p>Shrimp-like Decapoda: Caridea, Procarididea, Stenopodidea, Dendrobranchiata [Charles Fransen, Sammy De Grave]</p>	<p>Cryptic As for cryptic genetic diversity in shrimps, there is only one study, on a subgroup of <i>Alpheus</i>. This estimates that that potential species complex comprises 20 species rather than the one currently known. I would feel uncomfortable to projecting that ratio to all shrimps, as the level of cryptic species diversity must vary amongst groups. Overall, there is no basis for judgement in terms of all the shrimps groups Charles and I provided numbers for. Given the high number of available synonyms in the genera for which there has been a suggestion of cryptic species diversity (based on very limited genetic evidence) and the lack of combined molecular-morphological-colour pattern-ecological studies, it is impossible for us to provide even an appropriate guesstimate.</p> <p>References De Grave, S., and Fransen, C.H.J.M. (2011). Carideorum catalogus: the recent species of the dendrobranchiate, stenopodidean, procarididean and caridean shrimps (Crustacea: Decapoda). Zoologische Mededelingen, Leiden 85, 195–589.</p>
<p>Achelata, Polychelida, Enoplometoidea, Glypheoidea, Nephropoidea (marine lobsters) [Tin-Yam Chan]</p>	<p>Described, nominal, undescribed-collected Achelata: 142 accepted species, 229 nominal species names, and 10 new species residing in collection.</p> <p>Polychelida: 38 accepted species, 52 nominal species names, and 2 new species residing in collection.</p> <p>Enoplometoidea: 12 accepted species, 15 nominal species names, and 0 new species residing in collection.</p> <p>Glypheoidea: 2 accepted species, 2 nominal species names, and 0 new species residing in collection.</p> <p>Nephropoidea: 53 accepted species, 71 nominal species names, and 2 new species residing in collection.</p> <p>Undiscovered + cryptic For a group of generally large sized animals with high economic value, surprisingly the number of new species discovered in marine lobsters is still high even very recently. For example, nearly 11.3% of marine lobsters were only described in the last decade (<i>i.e.</i>, since 2000). From the still very steep discovery curve, no extrapolation for total number of marine lobster seems possible. Even to the most common and commercially important genera such as <i>Palinurus</i> and <i>Panulirus</i>, new species have been added in the last few years. Recent employment of molecular tools in separating cryptic and very similar species has contributed to the discovery of more lobster species as in other decapod crustaceans under this modern trend. Nevertheless, the high discovery rate of lobsters is no doubt more related to the revived large scale expeditions in the Indo-West Pacific. It is believed that many more marine lobsters with novel morphological diversity (<i>e.g.</i>, the new genus living fossil <i>Laurentaeglyphea neocaledonica</i> discovered in 2006) are still</p>

	<p>awaiting discovery. At least 14 new lobster species have already been found and awaiting formal description. Thus, it seems reasonable to assume that there are at least half more species (<i>i.e.</i>, more than 120 species) of marine lobsters are still undiscovered, with min-max bounds of 30–70%. Genetic diversity will be responsible for 1/10 of these new discoveries.</p> <p>References Chan, T.Y. (2010). Annotated checklist of the world’s marine lobsters (Crustacea: Decapoda: Astacidea, Glypheidea, Achelata, Polychelida). <i>Raffles Bull. Zool. suppl.</i> 23, 153–181.</p>
<p>Chirostyloidea and Galatheoidea [Enrique Macpherson, Karen E. Schnabel]</p>	<p>Described, nominal, undescribed</p> <p>Galatheoidea: 715 accepted species, 773 nominal species names, 300 new species residing in collection Chirostyloidea: 206 accepted species, 211 nominal species names, 250 new species residing in collection</p> <p>Undiscovered + cryptic After the rate of describing new species in the Indian and Pacific Oceans along the last decades, and considering the areas poorly known or scarcely sampled, we believe that the percentage of known species is c. 20% in Chirostyloidea and c. 35% in Galatheoidea.</p> <p>We are including in these estimations the species residing in collection and the undiscovered species. Therefore, the total number of unknown species would be: Chirostyloidea: 250 new species residing in collections, and 580 undiscovered; Galatheoidea: 300 new species residing in collections and 830 undiscovered.</p> <p>Usually, the term ‘cryptic’ is rather loosely applied, and usually there is some way of distinguishing the species when examined carefully after a dendrogram points to significant genetic differentiation. One problem in our group of course is that not a lot of detailed genetic datasets exist, at least not with good population sizes that may uncover true cryptic species, e.g., at extreme ends of the species range. We only have the examples from a few genera (with low number of species). In these genera the colour is also important, but it can be only used in fresh material. Considering these aspects, perhaps only 1 species per genus (less than 10%) could be nearly cryptic (although the colour can separate the species, but we ignore the colour in most species). Therefore, the percentage of cryptic species may be 1-5%. Nevertheless, until this percentage is not studied in rich genera, the numbers will be simple speculations.</p> <p>Reference Poore, G.C.B., Ah Yong, S.T., and Taylor, J. <p>Lithodoidea [Shane Ahyong]</p>	<p>Described 129 spp.</p> <p>Nominal 161 spp.</p> <p>Undescribed, collected 10 spp.</p> <p>Undiscovered The deepwaters of the Indo-Pacific are sampled in a very patchy way in</p>

	<p>terms of lithodid habitat. The northern Pacific has traditionally been regarded as the centre of lithodid diversity, but this seems to more likely represent an artefact of historical sampling. When expeditions to new areas in the Indo-Pacific, sampling slope depths, capture Lithodidae, these are usually new to science. Also, abyssal depths are poorly sampled worldwide, and lithodids can be expected to be present there. About 20 new species of lithodids have been described from the Indo-West Pacific in the past 5 years, based mainly on opportunistic sampling around Australia and New Zealand. The rate of discovery remains high, so a reasonable but conservative estimate would be at least 30 more species in the Indo-Pacific, especially of small sized species of Paralomis. Sampling in the Atlantic has been much more extensive historically, but new species have been described in the last few years. It could be reasonable to expect that at least 10 more species will be discovered in the South Atlantic off the coast of South America and West Africa. Therefore, a conservative estimate would be 40 undiscovered species worldwide.</p>
<p>Lomisoidea [Patsy McLaughlin, Rafael Lemaitre]</p>	<p>This is a monotypic superfamily, family and genus, endemic to Australia. No undescribed species known to exist in any collection; no undiscovered species thought yet to be found.</p>
<p>Paguroidea [Patsy McLaughlin, Rafael Lemaitre]</p>	<p>Described Right now there are 1,116 valid species on the books, although those numbers will change, both up and down, as revisionary studies continue.</p> <p>Nominal There are approximately 222 primary synonyms, with a couple of homonyms thrown in for good measure. I have included in the latter count, some taxa described as varieties (old works) and subspecies, but not all when it was pretty obvious that the author simply got confused.</p> <p>Undescribed, collected The number of paguroid species in existing museum collections that have yet to be identified and studied is hard to estimate. However, even in the collections of the Muséum national d'Historie naturelle, Paris, where paguroids have been actively studied for more than 30 years, the number of species still to be described probably exceeds 50. In museums lacking paguroid taxonomic expertise, such as several in China, a count of the number of unrecognized or incorrectly identified taxa would be very considerably higher (personal observations). Add to these estimates the potential for phylogenetically recognized new taxa and the number could easily double the currently known species. So, if you take in all the other museums the number is probably closer to 150 – 200.</p> <p>Undiscovered The accuracy of extrapolations from previous estimates of species diversity can be very misleading, at least as far as species of the Paguroidea are concerned. For example, in d'Udekem d'Acoz's (1999) inventory of European decapod species, 636 were reported and he said that on average, two new species was described each year. Of those 636 decapods, only 52 were paguroids and no new species have been added since his inventory. De Grave et al's (2009) checklist of worldwide genera and species put the number of Recent genera of Paguroidea at 120 and the number of species at 1,069. Similarly, McLaughlin et al.'s checklist (2010) lists 120 genera but with 1,106 Recent species. Clearly, estimates based on European species</p>

	<p>diversity in hermit crabs would give woefully low numbers.</p> <p>The apparent “explosion” in paguroid speciation is the result of expanded exploration in various parts of the world’s oceans, particularly the Indo-Pacific. In the last 20 years (1990—2010), 365 new species have been added to the paguroid inventory, the majority coming from the western Pacific and Indian Oceans: Diogenidae, 118 species; Paguridae, 213 species; Parapaguridae 28 species; Pylochelidae, 4 and the new family Pylojacquesidae with two monotypic genera. Only in the family Coenobitidae have no new species been added in the past 20 years.</p> <p>If exploratory efforts continue at approximately the same rate in more of the poorly known tropical and subtropical regions of the world’s oceans, the number of species could easily increase to a total number of 1500.</p> <p>Cryptic Asking for a guess of genetic diversity in the superfamily Paguroidea is akin to guessing the lengths of the longest and shortest straws in a bale of hay. There is only a minuscule amount known about the genetic make-up of hermits, so any idea of that diversity is simply impossible.</p> <p>References De Grave, S., Pentcheff, N.D., Ahyong, S.T., Chan, T.-Y., Crandall, K.A., Dworschak, P.C., Felder, D.L., Feldmann, R.M., Franssen, C.H.J.M., Goulding, L.Y.D., Lemaitre, R., Low, M.E.Y., Martin, J.W., Ng, P.K.L., Schweitzer, C.E., Tan, S.H., Tshudy, D., and Wetzer, R. <p>Brachyura [Peter Ng, Peter Davie]</p>	<p>Described As of January 2012: Total: 1,357 valid genera with 415 synonyms; 7,063 named species with 1,890 synonyms distributed across 98 families.</p> <p>Marine Brachyura: 1,127 genera with 362 synonyms; 5,668 species with 1,709 synonyms over 5 families.</p> <p>Freshwater Brachyura: 230 genera with 53 synonyms; 1,395 species with 181 synonyms over 5 families.</p> <p>Undescribed [Peter Ng]: we easily have at least 100 plus species in our collections which remain undescribed. [Peter Davie]: I have at least 60 species I know of, and then if we work on</p>

the estimate that there are about 50 new species discovered per year (that are not from our own groups), and make the assumption that these take 3 years from discovery to formal description (probably an underestimate), than we could add another 180 from the rest of the world. So potentially at least 310 species residing in collections awaiting publication.

Undiscovered

[Peter Ng]: the last 20 years has seen an average of 60-80 new genera and species every year (average one quarter are genera, rest are species). The number of new species recognised now versus what was recognised in the 1950s has seen a 57% increase. On these trends, and assuming we have another 40-50 years of sustained progress, an increase of another c. 3,000 can be expected.

However, over the years, we have found a fair number of cryptic species, based on molecular methods, that have subtle or good morphological characters that had been missed, dismissed or under-estimated. A grand total of 10,000 is therefore not unreasonable.

Because we rarely describe species solely on the basis of DNA, we can add the following 'cryptic' species numbers to the undiscovered "morpho-species" category (and not to the molecular cryptic part).

[Peter Davie] The following is the basis for a reasonable guess/estimate — Given about 5,700 marine species, if we assume 10% as being widespread, Indo-West Pacific species, then this equals 570.

Recent genetic and morphological studies on three widespread IWP crabs (Keenan *et al.*, 1998; Lai *et al.*, 2010; Ragionieri *et al.*, 2012) show that each includes 4 cryptic species. And this is reinforced as a more widespread decapod phenomenon, by similar results on a scyllarid lobster (5 cryptic species in the complex) (Burton & Davie, 2007).

So if we were to extrapolate as a minimum of 2 cryptic species per widespread taxon (*e.g.*, one Indian Ocean Basin and one Pacific Basin), then we would potentially have around another 570 unrecognised forms. If we were to allow each to include 4 cryptic species (which, as shown, appears to be the emerging common pattern), then this would blow out to about 1,700 extra.

So let's say for the Brachyura:

minimum unidentified cryptic species c. 550

maximum unidentified cryptic species c. 1,700

However: 1) this is based on a simple rough guess of 10% being widespread – we haven't had time to assemble the basic distributional data for all species yet (hopefully soon), so this is likely to be an under-estimate. 2) I don't have any personal experience of what level of cryptic speciation is likely/possible in the Atlantic.

The take-home message is that cryptic speciation is going to be an important factor in understanding marine brachyuran biodiversity, though it will take a substantial amount of work to get an accurate assessment. However if good patterns emerge from ongoing broad biogeographic, genetic and taxonomic studies, we may be able to use these data to develop surrogate models to get much more accurate predictions than are currently possible.

[Peter Ng] Agreed. Peter Davie has taken a semi-conservative approach here which ranges from an extra 560-1,700 within the 6,000 species we

	<p>have now. The Americans think we have much more, and that there could be as many as the same total again! Instinctively, I am more inclined to agree with Peter D's estimate as on the grounds that taxonomists generally tend to be more conservative. But the truth is probably in-between. So I would say that for operational reasons, we can take the higher estimate and double it <i>e.g.</i>, 3,400 cryptic species. I suggest this on the grounds also that many of these widespread species may have up to four "cryptics", more species are found to have wider ranges than expected with better surveys (so increasing the chance of cryptics), and we are still finding many new species at a high rate. So a higher number may be more realistic.</p> <p>Cryptic We don't know of any brachyuran species that has proved to be only definable based on molecular grounds without any morphological differences.</p> <p>References</p> <p>Burton, T.E., and Davie, P.J.F. <p>Gebiidea [Gary Poore]</p>	<p>Described 203 species</p> <p>Nominal 203 accepted + 22 synonyms = 225 species names.</p> <p>Undescribed, collected wild guess ~50</p> <p>Undiscovered ~100 – many areas especially deep water are unexplored, cryptic species are probable and the habitats in which these burrowers are found are hard to sample.</p>
<p>Axiidea [Gary Poore]</p>	<p>Described 455 species.</p> <p>Nominal 455 accepted + 51 synonyms = 506.</p> <p>Undescribed, collected A wild guess ~50.</p>

	<p>Undiscovered ~200 – many areas especially deep water are unexplored. Eg, Poore & Collin 2009 added 50% to the known fauna of Australia following sampling in WA and similar increments could be anticipated in other of the Pacific, the centre of diversity for this group. The probability of cryptic species in some widely applied names is high, and the habitats in which these burrowers are found are hard to sample.</p>
<p>Amphipoda [Jim Lowry]</p>	<p>Described Based on my checklist/catalogue there are currently 9,215 accepted species, of which 2,000 freshwater; 6,947 marine; 268 terrestrial (this includes the supralittoral beach-hoppers).</p> <p>Nominal Until we get full synonymies for all species the answer to this question is not known.</p> <p>Undescribed, collected Even in my own collection at the Australian Museum I don't know how many undescribed species are present.</p> <p>Undiscovered In a 4 year project we just finished, looking at about 30 genera in 7 families around the entire Australian coast and off-shore islands, we identified about 450 species of which about 120 were new – about 37.5%. We just got a new grant to describe those species. In the recent Great Barrier Reef project we identified about 230 species and about half were new species. However the majority of described species identified from the GBR study were new records for Australia. This was the first serious study of amphipods in tropical Australian waters and in fact the sampling was limited. In Australia we have now described about 1,150 species. If the unknown species rate is about 40% then we might expect 1,600+ species in shallow Australian waters. But if you add in new records of exotic species then it becomes less predictable and much higher. So that is kind of Australia. Probably the majority of world species come from Europe, North America, Japan, Madagascar/South Africa, New Zealand, Australia and Antarctica. If you start to look at all the places that are not well studied, including the deep sea, maybe you would double the current figure and estimate to about 20,000 species.</p>
<p>Cumacea [Sarah Gerken]</p>	<p>Described The number of species I have in my database at the moment is 1444.</p> <p>Nominal There are very few species name synonymies (30–40 names), but there are lots of generic revisions and generic synonymies (~150).</p> <p>Undescribed, collected I have in hand at least 45 undescribed species, 27 of which are in the process of being described at the moment.</p> <p>Undiscovered Excepting the North Atlantic and a few other relatively small well-studied regions, collections usually include 80–100% new species. If there are an</p>

	<p>estimated 1450 valid species, then that suggests that the number of undiscovered species, conservatively, is around 6000.</p>
<p>Isopoda [Gary Poore, Niel L. Bruce, Christopher B. Boyko]</p>	<p>Described 6,345 species. Figures were extracted from WoRMS and Schotte <i>et al.</i> (2008) by accumulating numbers of accepted marine species in Asellota (2114 excluding Asellidae, Stenasellidae), Phoratopodidea (1 species), Cymothoidea (2,615, including crustacean symbionts [fide Boyko] and excluding freshwater species defined by NL Bruce), Microcereberidea (27 marine of 48 according to Wilson (2008a)), Limnoridea (61), Sphaeromatidea (776, excluding freshwater species according to Bruce), Valvifera (603, excluding freshwater species), Oniscidea (148 in Ligiidae, Actaeiidae and Tylidae). Phreatoicoidea were excluded.</p> <p>Undescribed, collected 3,400 known but this could well be an underestimate because only some of the known collections were included: Antarctica 674*86% + 600 + 70 [Brandt, Loerz], Australia 320 SE slope, 118 WA slope, 50 SE shelf, 50 subtidal, 50 NW shelf [(Poore, et al., 1994), Poore, Bruce unpublished], NZ 300 [Brenke], some coral reefs 200 [Bruce], Gulf of Mexico 59 [(Wilson, 2008b)], Atlantic [284, DIVA, BIOZAIRE, MAUD, NODINAUT provided by CeDARMAR], MNHN, 71 [Bruce]. Family based estimates: Anthuroidea: 100; Sphaeromatidae: 100; Bopyroidea: 350, and Cryptoniscoidea: 100 [Boyko pers. comm.]; Missing data: Pacific deep-sea [Blake, Wilson], other museums.</p> <p>Undiscovered Using data from the deep sea that are largely Asellota Poore & Wilson (1993) estimated that less than 5% of species are known and recent samples in Australia suggest the figure is closer to 1% for asellotes but 17% for non-asellotes. CeDAMAR scientists believe for the Atlantic the figure is more like 10–20%. I would bias the figure more towards the lower figure to represent the larger and less sampled Pacific (5%). It could be argued that for non-asellotes in shallow water we have a better handle although many tropical species remain undescribed. Use 10% for these. So, undiscovered species, $2,114/5\% + 4,231/10\% = 85,000$. We would give a range of 60,000 to 120,000.</p> <p>How realistic is this? Many surveys in new areas turn up 100–300 new species. Meaning we could get another 79,000 species with 263–790 surveys. Sounds like a lot and there is a risk of faunal overlap. But (1) the world is a big place (2) the surveys we are talking about range in sampling size from 10 to 100,000 square metres (3) all are dominated by rare species and species accumulation curves that don't asymptote.</p> <p>It is worth remembering that sampling in the vast deep Pacific and Indian Oceans is only just beginning and asellote isopods dominate this habitat. Sampling in temperate and tropical Asia and Australia has consistently turned up numerous new species in the few families have been covered well. And as Niel Bruce reminds us "As far as Isopoda are concerned the highly diverse area of the 'Indo-Malaysian triangle' is not collected". As endemism is high there would be a large number of undescribed species in this region, easily into the 400 to 600 range if it as diverse as the Great Barrier Reef. East African coral reefs are similarly lightly collected, and indications are that these will be as diverse as the GBR.</p>

The flaw in our argument is that there is bound to be overlap between so many surveys. But one third of the fauna turns over along 3,000 km of the southern coast of Australia (in one biogeographic zone, see O'Hara & Poore 2000), and 80–90% from S to N Australia and again from Australia to Japan, and probably from Australia to Africa etc.

Cryptic

One introduces interesting practical and philosophical questions when asking for an estimate of undiscovered cryptic species. In the best study of the subject on isopods, Raupach *et al.* (2007) discovered as many as 5 species within a moderately widespread deep sea asellote nominal species. One could be tempted to multiply our estimate of morphological species by 5. The reason we would not is the fact that most described (and undescribed but recognised morphospecies) species are known only from a few individuals from the type locality or nearby. And there is plenty of evidence rapid species turnover with distance for deep-sea isopods, and probably other taxa.

Cases of multiple identifications over a wide geographic range are surprisingly few, relative to the number of species described. No cases like Raupach's are known from common widespread species in Europe or the US. There is some genetic variation in *Idotea balthica* but still only one species as far as is known.

So what you are asking is — would I recognise a new species on the basis of morphology if I found one in a new region? Our guess is probably yes. Raupach did not re-examine the morphology of his notional species but we would be surprised if they couldn't be distinguished. Morphologists are learning to look harder. There are plenty of examples of species swarms differentiated by slight morphological differences in Australia — see the work of Poore, Just, Wilson and Bruce. Plus, there are plenty of examples of so-called widespread species being later divided on the basis of morphology.

So in conclusion the number of undiscovered species which one could not distinguish morphologically is probably zero.

<p>Mysida & Lophogastrida [Kenneth Meland]</p>	<p>Described 1,180 species of mysids and 56 species of Lophogastrids (data from WoRMS).</p> <p>Nominal 1,743 mysids and 74 lophogastrids (data from WoRMS).</p> <p>Undescribed, collected Considering that there are few taxonomists actively working with Mysida, and that they are regularly describing new species upon discovery, we do not expect many undescribed species laying in their “private” collections? A quick enquiry to five taxonomists suggests approximately a total of 50 undescribed species in their collections (Brattegard, Meland, Murano, Hanamura, Price, pers. com.).</p> <p>On the same note, pertaining to the fact that only very few researchers work with Mysida taxonomy, we expect that benthic surveys might result in collections with unidentified Mysida specimens, albeit not so many, a wild guess would therefore be 80–100 undescribed already collected Mysida.</p> <p>The majority of Lophogastrida species are pelagic and when captured quite conspicuous. Owing to their obvious appearance as of being neither Caridea nor Mysida they do not go unnoticed and are usually identified and verified by Crustacea taxonomists. We therefore do not expect many undescribed species to be found in collections. On the other hand, considering the magnitude of pelagic sampling being conducted worldwide one can expect unsorted material in several collections that do contain Lophogastrida new to science; a conservative estimate would be approximately 10 undescribed species.</p> <p>Undiscovered Opposed to number of “already collected” undescribed species, the number of undiscovered Mysida waiting to be found is definitely much higher.</p> <p>When including Lophogastrida and freshwater species previous estimates of described species are as follows; 520 (Gordan 1957), 765 (Mauchline & Murano 1977), 1076 (Wittmann 1999). When compared to the current estimate of 1180 described marine species, we can safely say we are experiencing a steady increase of new species and there is no indication of saturation.</p> <p>According to Wittmann (1999), we expect that only 25% of known Mysida is described. This estimate is based on the idea that, on a global scale, less than 3% of the continental shelf has been sampled for Mysida. Here one must also bear in mind that the majority of benthic sampling is conducted with a grab, which is highly insufficient for capturing Mysida and therefore suggests a high degree of undersampling. Large areas of both the South American and Africa shelves, as far as Mysida are concerned, are</p>

practically unknown. Not to mention the deep-sea. In comparison, species diversity in well sampled areas (Mediterranean Sea, Caribbean Sea, North Atlantic and Pacific Oceans) are 3–5 times higher than a randomly selected shelf area, which suggests 2000–4000 undiscovered marine Mysida.

As the Lophogastrida are mostly found in the bathy- and mesopelagic zones of the world's oceans, they are quite often frequented in pelagic surveys. Recent sampling (MarEco project, 2005) between the Azores and Island as deep as 1000–4000 meter depths revealed an enormous biomass of five *Gnathophausia* and five *Eucopia* species. Interestingly only two of these are new to science, whereas the other eight species represent an expansion of geographical distribution from the South Atlantic, Gulf of Mexico, and Pacific Ocean. Similar results were also found in a study from the Gulf of Mexico revealing nine already described Lophogastrida species (Burghart *et al.*, 2007). In effect, regarding pelagic Lophogastrida biodiversity, their taxonomic history reveals increased distribution ranges and species synonymies resulting in an overall decrease of species numbers.

On the other hand, we are discovering new species of benthic living Lophogastrida. In this regard, owing to lower sampling efforts on the ocean floor, and vast areas not yet explored, following the same line of argument as in the Mysida (see Mysida section) (Wittmann 1999), species diversity of benthic Lophogastrida in well sampled areas (Mediterranean Sea, Caribbean Sea, North Atlantic and Pacific Oceans) are expected to be 3–5 times higher than a randomly selected shelf area. In effect a conservative estimate based on approximately 30 described benthic species suggests up to 120 undescribed Lophogastrida.

Cryptic

For cryptic species estimates very little has been published on "mysids", but we do have some personal observations that are useful in giving us the possibility to sketch some very rough ideas.

For Mysida, studies reveal that some species with relatively broad distributions (approximately 50 Mysida species can be considered to have a global distribution) had a genetic variation that resulted in splitting into separate species, more so for freshwater species (Audzijonyte 2005). But the opposite is also true; working with deep-sea benthic species I have found that a select few so-called cosmopolitans from the Atlantic and Pacific are remarkably identical in several genes. Also, I think we should bear in mind that although not “splitters”, mysida taxonomists do have a tendency of hunting for variation resulting in establishment of new species. And taking into account that our estimates suggest that only 28% of all Mysida are currently described, this sort of limits the possibilities of finding cryptic species.

For the Lophogastrida, the majority being pelagic, and with up to 15 cosmopolitans, one would expect that many of these actually are cryptic. Nothing is published on Lophogastrida, but I have a fairly good genetic sampling of *Gnathophausia* and *Eucopia* species from several water bodies. When receiving your most recent enquiry on new estimates I hurriedly compiled this genetic data. What the DNA sequences reveal, which I must admit was a bit surprising to me, is that the genetic distance between Indian Ocean, Atlantic Ocean, and Atlantic is surprisingly low. There are differences, but it takes the discussion more in the philosophical direction of

	<p>how to define species in the context of genetic variation. In other words no clear cut geographical separation in genes on broadly distributed Lophogastrida species, which forces me, considering their distribution patterns, to give a very conservative estimate of few expected cryptic species.</p> <p>Again, regarding cryptic species in Mysida and Lophogastrida, we know very little. Summing up, in the marine environment, we generally expect to find more species and maybe not so much splitting of what we have already described. For freshwater and cave systems, now that's a different matter. Much more needs to be done, and for the pelagic Lophogastrida and cavernicolous Stygiomysida, I expect more research in the near future, only time will tell.</p> <p>References</p> <p>Audzijonytė, A., and Väinölä, R. <p>Tanaidacea [Magda Blazewicz, Gary Anderson]</p>	<p>Described We have 1,153 species already described (data in WoRMS and Anderson, 2011).</p> <p>Nominal After going through my Peracarid database (Anderson, 2011), I have determined that there are about 70 subjective synonyms for various tanaids, and this is cross-checked with WoRMS.</p> <p>Undiscovered Based on the collections I have studied, 5% of tanaids might be known in the Antarctic and the Atlantic (relatively well studied regions). In contrast, the Pacific is less studied and probably only 2% is known. Following this there might be from 22,600 to 56,500 species of tanaids in world ocean.</p> <p>Cryptic I assume that some 10–15% might be cryptic taxa, but there is not enough</p>

	<p>evidence to underpin this. There is only one paper separating two species based on CO1. So there is no reliable data to let me judge how many cryptic species can be in tanaids, but in theory there should be many; otherwise how can you explain the cosmopolitan distribution of some taxa that are almost immovable, have no planktonic larvae and a short-life history?</p> <p>References Anderson, G. (2011). Tanaidacea Taxa and Literature <http://peracarida.usm.edu/>. Accessed on May 2011.</p>
<p>Thermosbaenacea [Damià Jaume]</p>	<p>Described Most species of this group appear in coastal oligohaline wells and caves. But these should not be considered as marine. The criterium is having been recorded in polyhaline (18–30 ppt) or euhaline waters. In that case there are 7 marine species.</p> <p>Undescribed, collected As regards numbers of marine taxa waiting in vials for a name, I have only a <i>Tulumella</i> from Caicos, and no news of others.</p>
<p>Copepoda [Geoff Boxshall]</p>	<p>Described 10,000 valid marine copepod species is an estimate and it is a conservative estimate because the 16,422 in WoRMS still includes so many synonyms. However, Ferrero <i>et al.</i> (2006) give an estimate of 12,000 for marine copepod species.</p> <p>The maximum figure I've seen for all copepods is 13,000 valid species and there are approaching 3,000 freshwater copepods. The number is obviously going to jump up when the cleaning is finished.</p> <p>Undiscovered and collected but undescribed In terms of the estimates of minimum and maximum numbers of unknown species out there, I suggest min: 30,000 and max 50,000 species. The bulk of the numbers coming from meiobenthos. The CeDAMar programme within the Census of Marine Life reported 800 different copepods from the Angola Basin (most of them new species), 300 new species from Crozex and another 300 new species from Nodinaut : http://www.isa.org.jm/files/documents/EN/Workshops/2010/Pres/CEDEMAR.pdf</p> <p>In shallower seas Ferrero <i>et al.</i> (2006) reported over 300 meiobenthic copepods from intertidal and subtidal sediments off Kuwait, virtually all of them new species. Outside of Europe Seas and in deeper waters, knowledge is very fragmentary.</p> <p>A significant number of new species will be parasitic or associated forms living symbiotically with vertebrate or invertebrate hosts. Justine <i>et al.</i> (2010) estimated that the number of described species of metazoan taxa, including copepods, parasitic on fish hosts represents about 3% of the total species richness. Currently we know over 2000 species of fish parasitic copepods, this may increase by an order of magnitude.</p> <p>Cryptic Ann Bucklin's work on near-surface pelagic copepods showed that some the so-called cosmopolitan species were hitherto unrecognized species complexes, but in other cases there really was global scale mixing and there</p>

	<p>was no evidence of cryptic species complexes. This applies to the surface plankton only — for virtually all benthic and parasitic copepods there are no data from which an estimate can be made.</p> <p>References Ferrero, T.J., Barnes, N., Arroyo, N.L., Bennell, G., Cornelius, P., Huys, R., Lee, C., Mustapha, M., Olafsson, E., Sebastian, S., and Bamber, R.N. Tantulocarida [Geoff Boxshall]	<p>Undiscovered Tantulocaridans were only recognised in 1983 and have since been discovered as ectoparasites on a wide range of peracaridan, leptostracan, ostracod and copepod crustacean hosts. Tantulocaridans occur from the tropics to the poles and at all depths. They are easily overlooked on the host and it is the discovery of the free-living larval stages in the marine meiofauna that has given insight into true level of species richness. Mohrbeck, Martínez Arbizu & Glatzel (2010) found 30 new species in a single series of samples from Drake Passage in the Southern Ocean. In depths exceeding 5,000m in the SE Atlantic, Mohrbeck and Martínez Arbizu reported the collection of 386 tantulocaridan larvae, and a high proportion of putative species were represented by single individuals. On the basis of only two quantitative analyses it isn't possible to robustly estimate global species richness; however an estimate of 1,000 seems quite conservative.</p> <p>References Mohrbeck, I., Martínez Arbizu, P., and Glatzel, T. (2010). Euphausiacea [Siegel Volker]	<p>Described 86 valid species worldwide.</p> <p>Nominal 148 species.</p> <p>Undescribed, collected None.</p> <p>Undiscovered None. Over the past 50 years only 3 new species have been described; this group of Crustacea is quite well studied and new species are hardly expected.</p>

<p>Stomatopoda [Shane Ahyong]</p>	<p>Described 468 spp.</p> <p>Nominal 580 spp.</p> <p>Undescribed, collected 52 spp.</p> <p>Undiscovered A conservative estimate is at least 200 more. Many widespread species appear to show regional variation that will likely prove to be distinct species. Molecular data will probably help uncover species flocks. Also, many species can be expected to be discovered de novo as coral reef habitats, especially those at moderate depths in the coral triangle are explored, and deeper, level habitats are sampled. New species are present in almost every collection to new or relatively unsampled areas. Significant parts of the western Pacific remain to be sampled as do many parts of the western Indian Ocean (generally poorly sampled). Moreover, stomatopods are rarely specifically targeted in sampling programmes and existing collections are largely the result of opportunistic or general sampling. Therefore, the diversity of stomatopods is much underestimated, and in many habitats, unsampled.</p>

- The presence of several undescribed leptostracan taxa from Friday Harbour, Pacific coast USA (Haney & Martin, 2000)
- Various authors referring to undescribed species (*e.g.*, Thiele, 1904; Wakabara, 1965; Johnson, 1970; Vetter, 1996).

Based on this data, plus my own knowledge of the Australian collections, I estimate there are at least 50 undescribed species held in museum collections, world-wide. It is possible this is an underestimate and the number may be closer to 100.

Undiscovered

The order Leptostraca is likely to be diverse and many authors support this view, suggesting additional species await discovery and description (*e.g.*, Haney & Martin, 2000). The low number of described species is a result of limited taxonomic effort and geographically limited sampling (G. Walker-Smith pers comm.; Haney & Martin, 2004; 2005).

Koçak *et al.* (2010) note that few species of Leptostraca have been described from the Mediterranean, while Olesen (1999) reports that western Indian Ocean leptostracans remain poorly studied. Haney *et al.* (2001) suggest the east coast of the USA is an understudied region, as is north coast of Australia (G. Walker-Smith pers. comm.).

Leptostracans have been recorded world-wide, from the intertidal zone to in excess of 6000 m (Haney & Martin, 2005). Exploration within this huge depth range is likely to result in the discovery of many, many more new species.

While it is difficult to estimate the number of uncollected, undescribed, leptostracan species I believe sampling needs to be more targeted if the “true” number of taxa is ever to be uncovered. Leptostracans are known to congregate in areas of high detritus (Vetter, 1995). They are also known to be scavengers of dead and rotting animal carcasses (*e.g.*, fish and crustaceans) (J.K. Lowry pers. comm. and G. Walker-Smith pers. observ.). Therefore, if sampling targets leptostracans, either by collecting in areas where the detritus load is high, or by using baited traps (across the full distributional depth range of the Leptostraca) it is possible hundreds of undescribed species will be discovered.

<p>Ostracoda (halocyprids) [Martin V. Angel]</p>	<p>Described I can only respond with regard to the halocyprids for which the number of accepted species is 254.</p> <p>Undescribed, collected I have on my shelves awaiting description ~60 species (of which I have made inroads into describing ~20). The majority of these are deep bathypelagic/abyssopelagic/benthopelagic. On the recent CMarZ cruises we sampled pelagically down to 5000m — we caught no novel species in the upper 2000m but 10% of the species caught below 2000m were novel (or undescribed). I would not expect to add any new species in the polar oceans in the upper 2000m, but in the Indian and Pacific Oceans novel species would be found. There was no sampling of the benthopelagic realm during CMarZ, but at the old IOS we started sampling to within 10m of the sea-bed to depths of 5500m — one sample from close to the NW African slope at 4000m caught 25 novel species. I have been looking at similar samples collected in the Southern Ocean during the AnDeep programme on the Polarstern and these contain another 10–15 novel species. No benthopelagic sampling has been carried out in the Indian Ocean or the Pacific.</p> <p>There seems to be a handful of benthopelagic species that occur both in the Atlantic and in the Southern Ocean, but my guess is that there is generally little in common between these communities in the major ocean basins of the World. Since I do not have a credible figure for the Atlantic where I know there are at least 50 and the total might be >100. So maybe in the</p>

Pacific and Indian Oceans one might expect similar numbers — maybe more in the Pacific because of its much greater area. So in the benthopelagic faunas we might expect at least a further 500 species.

Undiscovered

I have just had a paper published in *Deep-Sea Research II* 57 2173–2188 in which I conclude there are 153 species in the Atlantic. Almost no novel species were found at depths <1000m but from depths >3000m about 10% of the species were novel. The Atlantic has been well studied (as have the Polar oceans), but the Indo-Pacific is poorly known and almost nothing is known about the deepwater faunas. We know nothing about the scale of geographical distributions in deep sea communities — so is the Indo-Pacific one big unit or several. The distributions of the mid-water faunas tend to reflect the large scale circulation patterns (*i.e.*, water masses). So my intuition is that the deep water gyres in the Indian and Pacific Oceans will have their own assemblages of species — some of which (I guess <50%) will be shared. The Pacific is large enough for there to be an east/west divide — the Atlantic is not yet there do appear to be some small differences between east and west on either side of the mid-Atlantic Ridge. Delving into the circulation patterns is complex in the Atlantic, but more clear cut in the Pacific because of its shear scale. There are major differences in water column environments between east and west in the Pacific (there is strong oxygen depletion in the eastern tropical Pacific). So what — I would predict that the diversity in the Pacific and Indian Ocean are similar to that in the Atlantic. In the Atlantic when the benthopelagic fauna is fully known I would expect the numbers of species to increase to 200. I would expect the diversity in the Indian Ocean to be slightly smaller (after all it has very little northern Hemisphere), but it will be greater in the Pacific — especially as there are greater north/south and east/west divides. So let us guess that the total fauna in the Indian Ocean is around 150 and that of the Pacific is 400. The latter could be a gross underestimate if seamounts have their own specific faunas (certainly true for benthic species and maybe benthopelagic species). So then what is the communality between the different oceans — total guess 50%. Then we derived a total estimate for halocyprids of 200 (Atlantic) + 75 (Indian Ocean) + 150 (Pacific — assuming there is communality between the IO and PO). The Southern Ocean adds another 50 and the Arctic 5, which gives a ballpark estimate of ~480 halocyprid species — which is about double the number currently described.

Note that pelagic species have flexible boundaries to their distributions and are moved around by water currents and eddies. The ranges of benthic species will be far more restricted and the graininess of their distributions more complicated because of bottom topography. So the species richness of benthic species in both deep and shallow water can be expected to be much higher — perhaps by around an order of magnitude.

Cryptic

There is strong evidence for cryptic species in the halocyprid ostracods. In many 'species' there are differently sized populations that are segregated either geographically or bathymetrically. Recognising this segregation depends on the sampling regimes and often the bathymetric segregation goes unnoticed. Also routine processing of samples can lead to these size differences being missed. In all cases where these size differences are analysed morphologically good evidence is found to describe the different

	<p>sizes as distinct species. Recent sequencing studies have confirmed this segregation whenever it has been possible to check them out. The situation in the Atlantic is now reasonably under control and many (?most) of these cryptic species have been separated — although there are a number of complexes that remain unresolved.</p> <p>Examination of species from the NW Indian Ocean shows many species look 'similar' but show variations with the Atlantic forms. There have been no sequencing checks performed yet to see if my suspicions that many of the species are indeed different. Samples from around Indonesia (Celebes Sea) again yield species that kind of look the same but I suspect that careful analysis would show them to be different. I have been looking at samples from the N.E. Pacific and these impressions are even stronger — many species look sufficiently familiar for me to attach names but again I am convinced that given time and effort I can show them to be different.</p> <p>References Angel, M.V., Blachowiak-Samolyk, K., Drapun, I., and Castillo, R. (2007). Changes in the composition of planktonic ostracod populations across a range of latitudes in the North-east Atlantic. <i>Progress in Oceanography</i> 71, 60–78. Angel, M.V., Blachowiak-Samolyk, K., and Chavtur V.G. (2010). Atlas of Atlantic ostracods. http://www.nhm.ac.uk/research-curation/research/projects/atlantic-ostracods/atlas/index.html (accessed 4 March 2012).</p>
Ostracoda [Simone Nunes Brandao]	<p>Described In WoRMS, there is around 5800 recent, described species and a total of 5396 accepted species. Therefore, 93% of the described species are valid. Using this percentage, I estimate that from 7,000 to 9,500 described species, there are from 6,510 to 8,835 valid species described so far.</p> <p>Nominal Different previous estimations range from 7,000 to 9,500 (7,000 from Cohen & Morin, 1990; 8,000 from Horne <i>et al.</i>, 2002; 9,500 from Cohen <i>et al.</i>, 2007).</p> <p>Undescribed, collected From 1,000 to 2,000 species.</p> <p>Undiscovered Based on the data below (see Examples), from 20 to 78% of the ostracod species collected for a certain study are new to science. Using the numbers above this would mean that from 1625 to 32,000 ostracod species remain to be discovered. Examples: Machado <i>et al.</i> (2005) found 31 new species (46% of the total of 67 species) in 43 sediment samples from a small area (of 1 degree latitude, and 20' longitude) on the continental shelf off southeastern Brazil. Even for the most sampled and best well know area of the world oceans, the North Atlantic, 32% (28 species) of all 87 species were found to be new to science (Yasuhara <i>et al.</i>, 2009). Fifteen species were found in 2 corers collected from the Southern South Atlantic, three (20%) of these species were described as new. In deep waters of the Atlantic sector of the Southern Ocean, concerning the superfamily Bairdioidea 7 new species /78% of the total 9 species) collected</p>

	<p>during the ANDEEP project (Brandão, 2008). The ANDEEP samples also provided 16 new species of Macrocyprididae (73% of the total of 22 species) (Brandão, 2010)</p> <p>In shallow waters of the Sea of Japan, a total 35 new species (59%) were found from a total of 59 species (Zenina & Schornikov, 2008).</p> <p>In the Polynesian islands Huahiné and Rangiroa, 8 new species (44%) were described from a total of 18 collected species (plus six species left in open nomenclature because of scarcity of the specimens).</p> <p>Cryptic</p> <p>Estimating the number of cryptic species of marine, benthic ostracods is very difficult, because I only know of 2 papers (Yamaguchi, 2000 and Brandao <i>et al.</i>, 2010) dealing with marine genera or species groups. I did a search in Science direct and in our literature database in Hamburg, but did not find any new paper on this topic. Most (of the few) ostracod DNA studies at this level involve freshwater taxa. I don't think we should base our estimates on the freshwater papers because most (if not all) studied last taxa show asexual and mixed (asexual+sexual) reproduction, while marine ostracods reproduce sexually only. Marine and freshwater taxa should therefore show distinct genetic patterns.</p> <p>One of the works comprising COI sequences of a marine genus (Yamaguchi, 2000) doesn't cite the term "cryptic species" but geographically isolated, monophyletic and highly supported clades for all 4 species they studied are found in their tree. The number of monophyletic clades was always equal to the number of localities sampled for each species (<i>i.e.</i>, varied from 2 to 7).</p> <p>However, distinct mitochondrial lineages may be the result of other "processes" (<i>e.g.</i>, natural selection, hybridization, incomplete lineage sorting) than speciation. Only in the case of speciation would these geographically distinct clades be cryptic species. The second study was part of my PhD and is on 1 Southern Ocean genus. There were 7 morphospecies, 6 showed no evidence of cryptic species, while 1 morphospecies (also the most morphologically variable) showed evidence for the existence of four cryptic species. But again this pattern was observed only in COI gene.</p> <p>I conclude that, while both papers do show some evidence for cryptic species, extrapolating the number from 2 papers (2 to 7, or 0 to 4) to the entire marine realm is too risky. I would not dare saying any number.</p> <p>References</p> <p>Yamaguchi, S. (2000). Remipedia [Stefan Koennemann]	<p>Described 24 species.</p> <p>Nominal 25 species.</p>

	<p>Undescribed, collected We have 8 species awaiting description.</p> <p>Undiscovered We are describing 1–2 species per year; since I began working on the group in 2002, the number of species has more than doubled from 11 to 24 (not counting the 8 undescribed species). The exploration of new cave systems (within the main Caribbean distribution range) regularly yields new taxa, and I would expect as yet undiscovered remipedes in particular on Cuba and Jamaica, but also many other West Indian islands. However, we are also finding new species in well-explored caves. For example, we have identified three cryptic species using DNA taxonomy in more or less well-explored cave systems. Moreover, one of the enigmas concerning Remipedia is the fact that they occur sympatrically (with 4 to 6 species) in many caves. Based on a rough estimate of the number of (scientifically) unexplored caves + undiscovered occurrences of cryptic species + the possibility that remipedes may have a deep sea distribution (in addition to the "tip of the iceberg", the known anchialine caves at or slightly below sea level, as suggested by Boxshall, Iliffe and others), I could imagine that the currently known taxa might be 50% or even less of what is still out there. So this should give a min-max range of 20–50 species.</p> <p>Cryptic Circa 20% or between 5–9 species. With only 24 described species, the class Remipedia is small enough to give a fairly accurate estimate of cryptic species.</p>
Hexapoda (insects and Collembola) [Lanna Cheng]	<p>Described 2,037 species.</p> <p>Nominal 2,400 species names.</p> <p>Undescribed, collected I would hazard a guesstimate of around 30–60 undescribed species in collections around the world.</p> <p>Undiscovered It is difficult to guess how many marine insects remain to be discovered since very few entomologists work in marine environments. I guess we could use a conservative guesstimate of 30–100 species. Assuming there are some 2,000 marine insect species and some 30–60 (~2%) remain undescribed in various collections. These are likely to be 'accidentally' collected by non-entomologists. It is not unreasonable to assume that at least another 2% could be discovered as more marine habitats were to be visited by entomologists in the future. My guesstimate: 30–100</p> <p>Cryptic I really have no idea how many cryptic species will turn up in marine insects. A recent molecular study on 3 species of Pontomyia (Chronomidae) indicated that there may be several (less than 10) cryptic species. Ditto an earlier study on 1 oceanic species of Halobates. I am not aware of any similar studies on other species of marine insects.</p>

<p>Myriapoda [Anthony D. Barber]</p>	<p>It is often difficult to be clear as to whether myriapods found in or close to the littoral zone are, to use Silvestri's (1903) terminology myriapodi halofili genuini <i>i.e.</i>, confined to such habitats (obligate halophiles), myriapodi halofili indifferenti <i>i.e.</i>, occurring in both terrestrial and littoral habitats (facultative halophiles) or myriapodi halofili accidentali <i>i.e.</i>, chance occurrences (accidental halophiles). Such a situation may well be true of all "terrestrial" groups in which some species have invaded the littoral zone.</p> <p>Myriapods are essentially terrestrial groups of arthropods but representatives of all four classes from different orders, families and genera have colonised sea shore habitats and the situation is made more complex by species which appear to be genuini in one region but occur inland in another. The geophilomorph centipede <i>Hydroschendyla submarina</i>, for instance, is only ever recorded from seashores in northern Europe, the Mediterranean and Bermuda and is clearly genuini whilst <i>Pachymerium ferrugineum</i> is clearly indifferenti in much of its range. However, in many cases, where species are described from a single littoral site no such clarity is possible and the list in WoRMS may include some species which may later be considered accidentali.</p> <p>Class PAUROPODA About 500 species have been described altogether of which 5 seashore species are reported, all from Europe. The total number of littoral species in world must be much greater but impossible to estimate (? 40+); These are elusive animals, less than 2mm long, and are not often found by standard sampling techniques.</p> <p>Class SYMPHYLA About 200 species have been described in total; 4 (?5) apparently halophilic species are reported from England, Bulgaria and California. The total number of littoral species in the world must be much greater but impossible to estimate (? 30+); these are difficult animals to study and are not often identified to species level.</p> <p>Class DIPLOPODA Of the 10,000 or so described species of millipede four clearly halophilic species are reported from NW Europe, the Mediterranean Region, USA, Far-eastern Russia and Tasmania. In addition, two penicillate or bristly millipedes are also recorded; <i>Polyxenus lapidicola</i> by Silvestri from the Mediterranean (no subsequent definite records) and a <i>Chilixenus</i> sp. is reported from South Africa by Lawrence (1984). Total world halophilic species may be 20 or more as there are no records at all from western North America, Central & South America and the Caribbean, all of Asia and most</p>

	<p>of Oceania and littoral diplopods are often difficult to find.</p> <p>Class CHILOPODA About 3,000 species of centipedes have been described worldwide of which about 1,000 are members of the order Geophilomorpha which contains a number of littoral species. The total number of halophilic geophilomorphs recorded in a recent list (Barber, 2009) is 45. Most of these are from Europe, Western United States, the Caribbean, South America, Japan and Australia/New Zealand. There are few records from the Atlantic coast of USA or from Canada, very few African records and little from much of Asia other than Japan, Korea and Taiwan. It is highly improbable that there are no species occurring on these coasts. In addition it is possible that some species for which no habitat data is given (<i>e.g.</i>, for California / Baja California, South Africa, New Zealand) may well be halophilic and also finding littoral species in some habitats (<i>e.g.</i>, rock crevices) is not always easy. An estimate of 100 plus species from around the world seems reasonable.</p> <p>References Barber, A.D. (2009). Littoral myriapods: a review. <i>Soil Organisms</i> 81, 735–760. Lawrence, R.F. (1984). <i>The Centipedes and Millipedes of Southern Africa</i>. Cape Town & Rotterdam, A.N.Balkema Silvestri, F. (1903). Fauna Napoletana. <p>Brachiopoda [Christian Emig]</p>	<p>Described 388 species.</p> <p>Nominal species # is not available.</p> <p>Undescribed, collected None.</p> <p>Undiscovered Not estimated.</p> <p>Cryptic Not estimated.</p>
<p>Bryozoa [Dennis Gordon, Phil Bock]</p>	<p>Described ~5,900 species.</p> <p>Estimated undescribed and undiscovered 2,800–5,200.</p> <p>Some recent (past 20 years) comprehensive studies of genera (<i>e.g.</i>, <i>Bryopesanser</i>, <i>Buffonellaria</i>) and entire small families (<i>e.g.</i>, Eurystomellidae, Macroporidae) have yielded increases in species numbers of c. 100-650% and this level of increase appears likely to be the case as more revisionary work is done and new faunas described. A major problem is the number of species described in the 19th century that have never been revised/revisited, and no-one knows what would be the best genus for them</p>

	<p>now. At least they are available names.</p> <p>Undiscovered + Cryptic The bryozoan fauna for Australia is about 1,000 accepted, with another ~1,000 yet undescribed, with many areas not yet sampled. This would give 50% known. New Zealand is better known (including >320 known-undescribed), with better sampling density, but even shallow-water collecting is still yielding new taxa. Europe is much better known; the Caribbean would have many undescribed (in the Smithsonian), and many uncollected; the rest of the tropics are going to prove very productive when they are thoroughly sampled.</p> <p>Based on field experience in the past two years, coral- reef environments below 20 metres are particularly rich in Bryozoa, with sampling by SCUBA the only way to sample adequately. There has been so little done across the reefs of the world that we cannot estimate the variation between near or distant reef groups. Certainly the fauna from the northern Great Barrier Reef (Lizard Island) and the southern Great Barrier Reef (Heron Island region) show major differences. Tilbrook (2006) determined that 20-30% of bryozoan species from newly sampled areas of the tropical Indo-Pacific are new. There is a similar percentage for the New Zealand deep sea, in some cases higher, and such will be the case when other parts of the slope-to-abyssal fauna are sampled.</p> <p>We would estimate 2,800-5,200 undiscovered species of Bryozoa, of which the cryptic component might be 350-950, although the latter is difficult to estimate. Cryptic species discovered in the past couple of decades by genetic means (predominantly Ctenostomata like some species of <i>Alcyonidium</i>) have subsequently been discovered to have discriminating life-history or anatomical features that were previously overlooked, so that they cease to remain cryptic as defined. In this case it is a matter of failing to perceive characters. Generally bryozoans have reliable morphological characters and workers are getting better at discriminating species. We would expect the greatest proportion of cryptic species to be among the orders Ctenostomata and Cyclostomata in which there is a relative paucity of characters, confounded by homoplasy, compared to the Cheilostomata.</p> <p>References Tilbrook, K.J. (2006). Cheilostomatous Bryozoa from the Solomon Islands. Santa Barbara Museum of Natural History Monographs 4 (Studies in Biodiversity 3), 1–385.</p>
Cephalorhyncha Nematomorpha [Andreas Schmidt-Rhaesa]	<p>Undescribed, collected Rough estimate: 70 species.</p> <p>Undiscovered From temperate regions, there are about 10% new species in samples, in tropical regions these are up to 50%. Considering which regions have been sampled I estimate that the species number is about twice as high as the known number (around 600).</p> <p>Cryptic There are no studies on cryptic species in this taxon, but sampling is highly accidental and therefore incomplete.</p>

Kinorhyncha [Birger Neuhaus]	<p>Described 180 species based on description of adult specimens + 48 species based on description of juvenile stages (valid in the sense of ICZN but usually not accepted by scientists, because many species based on the description of juveniles may/will turn out as synonyms of species based on the description of adults)</p> <p>Nominal ca. 228.</p> <p>Undescribed, collected The largest collections of undescribed kinorhynch specimens are housed by the National Museum of Natural History, Smithsonian Institution, Washington D.C., the Museum für Naturkunde Berlin, and the Zoological Museum, Natural History Museum of Denmark, Copenhagen. It is estimated that these collections include 250–350 new species.</p> <p>Undiscovered Only the coastlines of Europe and North America have been sampled for the meiobenthic Kinorhyncha in some detail with individual records from all over the world (Zelinka 1928; Higgins 1983; Adrianov & Malakhov 1999; Neuhaus & Higgins 2002). Almost every haul on the continental shelf or in the deep sea reveals new species of Kinorhyncha (Hoernle <i>et al.</i>, 2003; Neuhaus & Blasche 2006; Sørensen 2006, 2007, 2008; Sørensen <i>et al.</i>, 2000, 2007, 2009, 2010a, b ; Sørensen & Rho 2009; Sørensen & Thormar 2010; Werner <i>et al.</i>, 2009). Therefore, at least 1,000–2,000 species of Kinorhyncha can be expected to live in marine environments.</p> <p>References Adrianov, A.V., and Malakhov, V.V. (1999). Cephalorhyncha of the world ocean. <p>Loricifera [Antonio Todaro; Reinhardt Møbjerg Kristensen]</p>	<p>Described 32 species described and valid.</p> <p>Nominal 32 species names.</p> <p>Undescribed, collected 123 specimens.</p> <p>Undiscovered About 1,000 species.</p>
<p>Chaetognatha [Erik V. Thuesen]</p>	<p>Described 129 species described and accepted as valid in WoRMS as of July 5, 2012.</p> <p>Nominal 280 species names listed in WoRMS, including those listed as <i>nomen dubium</i>, and synonyms, including those changed due to new combinations.</p> <p>Undiscovered Total number of living chaetognath species is guesstimated to be ~180.</p> <p>Cryptic Two species of chaetognaths have been investigated for cryptic speciation, <i>Parasagitta setosa</i> (Peijnenburg et al., 2006) and <i>Caecosagitta macrocephala</i> (Miyamoto et al., 2010b). Mitochondrial DNA data suggest that cryptic species exist for both of these species. Two cryptic species are inseparable from <i>Parasagitta setosa</i> based on morphology and nuclear DNA (Peijnenburg et al., 2006), and similarly, two cryptic species are</p>

	<p>inseparable from <i>Caecosagitta macrocephala</i> using morphological and nuclear DNA analyses (Miyamoto <i>et al.</i>, 2010b). If every chaetognath species displays the same amount of cryptic speciation as <i>P. setosa</i> (a neritic species from the eastern North Atlantic Ocean) and <i>C. macrocephala</i> (a cosmopolitan deepsea species), the estimated number of cryptic chaetognath species would be 256, tripling the number of total chaetognath species. This high number is based on COII and COI data for <i>P. setosa</i> and <i>C. macrocephala</i>, respectively. On the other hand, using the results of nuclear DNA analyses, a low estimate of the number of cryptic chaetognath species would be zero. Due to the extremely small mitochondrial genome size, the smallest in the Animal Kingdom (Faure and Casanova, 2006; Miyamoto <i>et al.</i>, 2010a) and the likely occurrence of ribosomal DNA allopolyploidy (Telford and Holland, 1997; Barthelemy <i>et al.</i>, 2007), much more work needs to be undertaken in order to ascertain whether or not cryptic speciation has actually taken place in the Chaetognatha.</p> <p>References Barthelemy, R.M., Grino, M., Pontarotti, P., Casanova, J. P., and Faure, E. (2007). The differential expression of ribosomal 18S RNA paralog genes from the chaetognath <i>Spadella cephaloptera</i>. <i>Cellular & Molecular Biology Letters</i> 12, 573–583. <p>Ascidiacea [Adriaan Gittenberger, Marc Rius, Billie Swalla, Noa Shenkar, Rosana Moreira da Rocha, Gretchen Lambert, Xavier Turon]</p>	<p>Described 2,874 species (Shenkar & Swalla, 2011; Shenkar <i>et al.</i>, 2012).</p> <p>Nominal Estimate = 5,000 (based on WoRMS).</p> <p>Undescribed, collected Estimate = ~ 500.</p> <p>Many collections from different places in the world held in museums and research institutions remain to be studied. The most recent ones include alcohol preserved vouchers amenable to genetic analysis, though most museum samples were first preserved in formalin and then transferred to</p>

ethanol. Thus, a substantial number of species presently undescribed are likely to surface from the study of these collections. If DNA analyses protocols can be optimized to also include formalin preserved tunicate material (as was successfully done in other marine taxa; Palero *et al.*, 2010) we expect that this will greatly nuance studies of the Ascidiacea.

Undiscovered

Rosana Moreira da Rocha conducted a review of 37 articles on ascidian fauna published between 1980 and 2009: “8 articles with less than 10% of new species, 15 with 10–30% of new species, 10 with 30–50 % and only 4 with more than 50%”. Based on these numbers, we all agree that projecting 100% of increment beyond the known species is too much. Since there are almost 3000 valid species, 4000–4500 is a better estimate of the number of ascidian species.

Examples per region

Africa (Marc Rius): The ascidians inhabiting African waters are poorly studied. This is demonstrated by the fact that every time a taxonomist studies a particular region in Africa, a number of new species are described. For example, 10 and 17 new species were described by Millar (1955) and Millar (1962) respectively when he studied samples from South Africa. The same trend has been found when different taxonomists revise a particular region — Monniot *et al.* (2001) described 22 new species from South Africa. This is not region-exclusive and taxonomic studies conducted in different parts of Africa have shown similar trajectories (*e.g.*, Monniot & Monniot 1994 described two new species from the central west African coast; Pérez-Portela & Turon 2008 found a new species inhabiting waters of Kenya, Tasmania and Madagascar; etc.).

Australia (Williams *et al.*, 2010: table 1): About 33% of the ascidians found during a recent inventory of species in Australia, were found to be unknown to science.

Central & South America (Rosana Moreira da Rocha):

We still have many species to be discovered in the Caribbean, since most of the islands were never surveyed and we see that we have at least 1–2 endemic species each every time we start collecting. So, we may have a very conservative guess calculating 2 new species per island or country.

Panama: There are 80 spp. In the Bocas del Toro region (Caribbean side) among which more than 15 species (20%) are to be described (2 *Pyura*, 1 *Symplesma*, 1 *Eudistoma*, 1 *Ecteinascidia*, 10 didemnids, 1 Clavelinidae, 1 *Eusynstyela*).

Venezuela: In only one site surveyed in April 2009 we found 29 species among which 1 or 2 new *Styela*, 1 new Botryllid, 1 new *Lissoclinum* (but it is the same species in Panamá) (~14% new sp).

Brazil: We have around 110 registered and more than 20 species in our collections to be described that we already know are new species (~15%) (2 *Aplidium*, 10 didemnids, 1 *Distaplia*, 2–3 Botryllids, 1 *Rhopalaea*, 3–4 *Eudistoma*).

Ecuador: We also have material from Galapagos with lots of new species to be described: 3–4 *Eudistoma*, 5–6 *Aplidium*, 4 *Ascidia*, 2 Botryllids, 2–3

didemnids).

California, U.S.A. Continental Shelf: (Gretchen Lambert) A U.S.A. Department of the Interior Minerals Management Service 1983–89 conducted an assessment of long-term changes in the biological communities of the California Continental Shelf from the Santa Maria Basin and western Santa Barbara Channel. It was the only sampling of these areas since 1904 in which ascidians were identified. Of the 20 species collected, 16 were identified to species, the other 4 only to genus, 3 were new species (Lambert, 1993). Six of the 16 identified to species were the same as collected in 1904 from these areas (Ritter, 1907). Of the 14 species collected in 1904, 4 were abyssal and not found in the present study. Thus only 4 of Ritter's (1907) 14 described ascidian species were ones that he found but were not collected at similar depths about 90 years later (Lambert, 1993).

Mediterranean (Xavier Turon): The number of new species described or recorded in the Mediterranean sea has leveled off during the last couple of decades (Coll *et al.*, 2010 Fig 13D), but is still increasing, particularly due to the application of new molecular techniques to unsolved taxonomic problems. So, even in the “well-known” Mediterranean, with 229 species described (Coll *et al.*, 2010, Appendix S2), we estimate that 30–50 species remain to be discovered.

Red Sea and Mediterranean (Noa Shenkar): There still are quite a few new species to be discovered. Tel Aviv University includes ~500 specimens from the Red Sea and Mediterranean coasts of Israel. There are 2 recently described new species (Shenkar 2012). Brunetti published last year a new *Botryllus* sp. from the Mediterranean coast of Israel, and there are 2 new species from the Red Sea of *Rhopalaea* and *Ascidia* that still need to be described.

General (Gretchen Lambert): Most of us have estimated that there are about 3,000 extant spp., with several hundred in this number yet to be discovered/described. The ascidian fauna of the tropical West Pacific is however still very poorly known, with recent works featuring overall ~50% of species being new to science (*e.g.*, Monniot & Monniot 1996, 2001, 2008). Just as Rosana Moreira da Rocha is finding new spp. around each island in the Caribbean, so this is true in the W. Pacific only on a much more gigantic scale. Therefore, we asked the opinion of Françoise Monniot, in France. She said “In my opinion (with approximate information from my own data base) about 4,000 species may be valuable ones. It is impossible to evaluate the number of unknown species, many are described every year and so many parts of the world have never been investigated!”.

Cryptic

We discussed the number of species that may be discovered in the future with molecular techniques. We all agree that molecular techniques have shown that cryptic speciation is frequent in ascidians, and that they are excellent tools to discover new species. However, molecular techniques should not be considered without also considering the morphology of the species. Recent studies on ascidians revealed that the coupling of genetic and morphological approaches is fruitful and that there are always morphological characters that can distinguish among the species (*e.g.*, Perez-Portela *et al.*, 2007).

We believe that there should not be a distinction between a “morphological perspective” versus a “molecular perspective”, as both methods contribute to taxonomy. Adding 500 species that may be discovered based on molecular techniques sums up our estimation to 4000–5000 species.

Larvacea [Russ Hopcroft]	<p>Described 67 valid species (all in WoRMS).</p> <p>Nominal 75 subjective synonyms (all in WoRMS).</p> <p>Undescribed, collected I have 2, I know of 2 others at MBARI (California) from ROV video records. Most new ones are deep-water and require collection by an ROV. There are probably less than 5 other people capable of knowing if they have discovered something new!</p> <p>Undiscovered 63, based on Hopcroft (2005). I stick with those numbers — especially when one considers they do not include cryptic species that would show up based on genetic work.</p> <p>Cryptic There is likely to be high cryptic diversity in the larvaceans, because many species have very broad distributions, with occurrences in multiple oceans. Thus far, no one has been able to find a COI primer that works for this group, so there is no information on how extensive cryptic species might be! Based on what I've seen for other groups this could be in the order of 2–5 folds.</p> <p>References Hopcroft, R.R. (2005). Diversity in larvaceans: How many species?, in: Gorsky, G. <i>et al.</i> (2005). Response of marine ecosystems to global change: ecological impact of appendicularians. pp. 45–57.</p>
Thaliacea [Laurence P. Madin]	<p>Described 79 species in 27 genera: Doliolids: 10 genera, 26 spp, Salps: 14 genera, 45 spp. Pyrosomes: 3 genera, 8 spp.</p> <p>Nominal Same as described.</p> <p>Undescribed, collected I'm not aware of any undescribed species already collected, but would guess not more than 5.</p> <p>Undiscovered I doubt there are more than another 10% of the current thaliacean species yet to be discovered, or about 8.</p>
Pisces [William Eschmeyer]	<p>Described + nominal + Undiscovered See Eschmeyer <i>et al.</i> (2010).</p> <p>New values of described and valid genera and species can be found online via Google (Catalog of Fishes) or at</p>

	<p>http://research.calacademy.org/ichthyology/catalog. New taxa in 2011 were 340 new species and 25 new genera. New online versions of the Catalog of Fishes are posted online about every 6–8 weeks.</p> <p>Undescribed, collected I would estimate that the number might be 500 (10% of the 5,000). Some would be in combination with new discoveries — find new species from new specimens, then reinforce with museum specimens.</p> <p>Cryptic The number of cryptic species in fishes is probably small and mostly among reef species. Recent papers reveal a few, maybe 15 in the last 5 years. There will be more, but not too many. Let's say less than 200–300. Fish have many characters, and most are fairly easy to define as so-far known.</p> <p>Reference Eschmeyer, W.N., Fricke, R., Fong, J.D., and Polack, D. (2010). Marine fish biodiversity: A history of knowledge and discovery (Pisces). <i>Zootaxa</i> 2525, 19–50.</p>
<p>Sirenia [Caryn Self-Sullivan, Daryl Domning]</p>	<p>Described 4 recent marine Sirenia spp. <i>Trichechus inunguis</i> is only found in fresh water and in that sense is not a "marine" species. However, it is found along the seaward edge of the Amazon River's delta and is thus "marine" in the geographic sense, even though that coastline is always bathed in fresh water due to the Amazon's enormous discharge.</p> <p>Nominal 35 nominal species names, data from WoRMS.</p> <p>Undescribed, collected None.</p> <p>Undiscovered None.</p> <p>Cryptic For Sirenia (Mammalia), there are 4 recognized living species, and I would estimate zero cryptic species, based on the fact that a fair amount of work has been done on phylogeography of the 3 manatee species using mtDNA (and some work on the dugong), and no signs of cryptic species have turned up that I know of. Also, large mammals in general are not known to be prone to a lot of cryptic speciation, so a priori I wouldn't expect it in sirenians.</p>
<p>Cetacea [William Perrin]</p>	<p>Described The number of accepted species is 87.</p> <p>Nominal There are 1,271 species names of Cetacea in WoRMS.</p> <p>Undescribed, collected No new species at present.</p> <p>Undiscovered + Cryptic</p>

	<p>Based on the description of four new species in the last two decades, there may be a couple more out there. It has been suggested that the killer whale and the common bottlenose dolphin should each perhaps be split into two or more species. To give a number: 1–5 species for undiscovered/unknown for Cetacea, and 1–3 cryptic species.</p>
<p>Reptilia [Peter Uetz]</p>	<p>Described ~ 110 marine reptiles.</p> <p>Nominal ~ 600 (including misspellings).</p> <p>Undescribed, collected Just out of experience, I am sure that there are undescribed species, but it is almost impossible to guess that number.</p> <p>Undiscovered The rate of new reptile species described/discovered has been steady for over a hundred years, in fact, accelerating, so it is pretty much impossible to predict how long this trend will last. Of the 100+ marine reptiles, about 4% (4) have been described during the past 10 years. However, during the 20 years before that, only 6 new species were described but all of them by the same author (Kharin). That is, someone just made an effort and found single-handedly all new species described in 20 years. There may be up to another dozen truly marine species and another dozen undiscovered species occurring in coastal/brackish/mangrove habitats, but probably not more than that.</p> <p>The longer I think about it — maybe you should put 20–30 undiscovered species down, instead of 10. It is a long shot, but it sounds unlikely that the huge oceans harbor only 10 new species. Again, it is really unpredictable.</p>
<p>Aves [Mark Tasker]</p>	<p>Described 641 species (based on WoRMS).</p> <p>Nominal My guess is quite a low number of synonyms, though seabirds tend to be large and reasonably well described.</p> <p>Undescribed, collected My guess is 30–50 species, but many taxa have been described in the collections, just not at species level.</p> <p>Undiscovered My guess is also 30–50 species. One or two of these may presently be known from specimens but assumed extinct.</p> <p>Cryptic Only very few bird species seem to be discovered by genetic analysis; more often these are found by plumage or song variation, which may then be backed up by genetics. So I would say on the basis of current track record that there are very few extra cryptic species to be discovered using genetics.</p>
<p>Antipatharia [Dennis M. Opresko,</p>	<p>Described There are about 250 valid described species.</p>

Tina Molodtsova]	<p>Nominal If we include synonyms, and taxa that cannot be identified — about 280 species.</p> <p>Undescribed, collected From our examination of collections yet to be published on, we are estimating that there are 50 to 75 new taxa.</p> <p>Undiscovered We think that there may be as many as 50 to 100 still to be collected.</p> <p>Cryptic Concerning the Antipatharian corals, genetic diversity estimates would be very difficult at this time because most of the genetic studies to date have been conducted on mitochondrial markers which, for anthozoan cnidarians, do not provide an adequate level of variation to identify cryptic species.</p>
Actiniaria [Daphne G. Fautin]	<p>Described 1,093 currently considered valid species.</p> <p>Nominal 1,454.</p> <p>Undiscovered I have no basis for providing a number for this. Although new species are being described, synonyms are also being proposed, so the number is not climbing rapidly.</p> <p>Reference Fautin, D.G. (2011). Hexacorallians of the World. http://geoportal.kgs.ku.edu/hexacoral/anemone2/index.cfm.</p>
Corallimorpharia [Daphne G. Fautin]	<p>Described 47 currently considered valid species.</p> <p>Nominal 55.</p> <p>Undiscovered I have no basis for providing a number for this. Recently described species are largely from the deep sea. There is a lot of diversity in the shallow tropics; names are not easily assigned to all types but many names have been proposed that are now of uncertain application, so names may exist for most organisms, and the real work lies in figuring out what name belongs to what species.</p> <p>Reference Fautin, D.G. (2011). Hexacorallians of the World. http://geoportal.kgs.ku.edu/hexacoral/anemone2/index.cfm</p>
Ceriantharia [Tina N. Molodtsova]	<p>Described 137 species.</p> <p>Nominal</p>

	<p>160 species names.</p> <p>Undescribed, collected 4–6 species.</p> <p>Undiscovered 15–25 species.</p>
<p>Zoantharia [James Davis Reimer]</p>	<p>Described 101 species. Likely low but on the safe side, the reason this is lower than currently in WoRMS is I am certain <i>Palythoa</i> and <i>Zoanthus</i> have many synonymous names.</p> <p>Nominal 453. Total from WoRMS plus Hexacorallians of the World (Fautin, 2011) databases. There are likely a few more names out there in obscure literature, but this is a good estimate.</p> <p>Undescribed, collected 30. Undoubtedly more than this in reality, but only based on my firsthand knowledge of specimens. This number includes species that will likely have to be placed within new genera and families – based on our DNA analyses of some undescribed specimens the higher (>generic) level diversity of this order is much higher than is now known (<i>e.g.</i>, Fujii and Reimer, 2011).</p> <p>Undiscovered 180–380, based on the rates at which we are finding new species, total derived from estimated and conservative numbers of undiscovered species for each genus.</p> <p>Thus, the total minimal number of species in this order looks to be (101+30+180) around 300 species, with conservative estimates, but could be up to 500 based on what happens with putative synonyms, etc.</p> <p>The biggest problem facing zoanthid taxonomy is the very large number of potential synonyms. Thus, for many species, we really have no idea if they are valid or not, particularly in the genera <i>Palythoa</i>, <i>Zoanthus</i>, and <i>Epizoanthus</i>. Still, based on observations of <i>Zoanthus</i> and <i>Palythoa</i>, I think it is very likely there are many synonymous species in this order. Sorting this out will take many years of examination.</p> <p>Also, there appear to be many species still undiscovered, from the deep sea, or other unexamined localities and ecosystems (<i>e.g.</i>, Reimer and Sinniger 2010). So, the taxonomy of this order can be characterized as:</p> <ol style="list-style-type: none"> a. chaotic (see Burnett <i>et al.</i>, 1994; 1997; Ryland and Lancaster, 2003), b. much synonymy, specimens redescribed from different localities, etc. (see numerous papers by Carlgren and Pax), c. much diversity remaining to be discovered (<i>e.g.</i>, Reimer and Fujii, 2010; Fujii and Reimer, 2011). <p>Cryptic The ratios for zoanthids is 1.2–2.5 per morpho-species; but we have only limited molecular evidence for this. So if total morpho-species = 311–511, than 1.2–2.5 means the number of add-on cryptic species is (311*0.2)=62 and (511*1.5)=766 (rounded to 60 and 760).</p>

Scleractinia [Bert Hoeksema; Stephen Cairns]	<p>Described</p> <p>Azooxanthellate: 720. The number at the end of 1999 (Cairns et al., 1999) was 669. Since then, 48 51 species have been described, 7 synonymized, and 10 added from previously forgotten sources, for a net gain of 51–54. The actual rate of growth is 48–51/110.5, or 4.6 species per year. This is down from an annual rate of 7.03 based on 30 years: 1968–1998 (Cairns, 1999) and 6.9 based on 7 years: 2000–2007 (Cairns 2007), consistent with a projected decline in the growth rate predicted by Cairns in 1999. But, the growth rate is highly dependent on how many people are actively engaged in the study of zooxanthellate taxonomy, which today is one (Marcelo Kitahara). Nonetheless, I persist that the growth rate will continue to decline and the species accumulation curve will become more horizontal. During the same time, 4 new genera were described and one synonymized, for a net gain of 3: 117 to 120.</p> <p>Zooxanthellate: 860 (minus ca. 60 that are likely to be synonymized again) = 800. Many taxonomic changes at family and genus level are foreseen to take place in the near future as a result of molecular methods (e.g., Benzoni et al., 2007, 2011; Fukami et al., 2008; Nunes et al., 2008; Huang et al., 2009, 2011; Budd et al., 2010; Kitahara et al., 2010; Gittenberger et al., 2011).</p> <p>Nominal</p> <p>Azooxanthellate: 720 + 365 junior subject synonyms (and a few junior homonyms), or 1,085 names. The synonymy rate is thus 365/1085, or 33.6%, a similar percentage (34.1%) reported by Cairns (2001).</p> <p>Zooxanthellate: 800 x 3.5 = 2,800 (based on 2 taxonomic revisions (Hoeksema 1989, Wallace 1999) I come to an average of 3.5 names per species.</p> <p>Note the difference in synonyms between deepwater corals and the easily accessible reef corals.</p>

Undescribed, collected

Azooxanthellate: Number of undescribed new species based on collections in hand: Marseille (6), James Cook/Paris Museum (9), NMNH (73), or a total of about 88, some of which were published as species A, B, C, etc (see Cairns in Roberts, *et al.*, 2009).

Zooxanthellate: 5 that I need to describe. (There are 10 categorized as nomen nudum but I do not know whether they are present in collections, and that is why they are still nomen nudum).

Undiscovered

Azooxanthellate: In my 1999 paper I used three methods to estimate this number, which I have now re-evaluated.

A. Partial Inventory Method, based on percentage of new species occurring in large unworked collections: In 1999 this method estimated a total of 781 species; now the estimate based on this method is 768. (I think this occurred because many of the undescribed species are singletons or just confusing, so they are put aside and did not contribute to a higher percentage of new taxa in a previous revision.)

B. Method of Hammond (1992), which is based on the yearly growth over the last decade compared to the overall growth rate since 1758, and then some rather subjective guesses. These numbers suggest 800–1,440 total species, or an additional 80–720 species. C. Intuitive: having worked with the group for 35 years I feel as though there are about 1,050 total species, or another 330 to describe.

Zooxanthellate: 100. Since 1999, 142 species have been described as new. Several of these are to become synonymized. New species are sibling species (discovered by DNA analysis), strict endemics, or based on old-fashioned standard collection revision work. Most are the result of increasing fieldwork activities worldwide, including remote places, and more an increasing number of observer's people (divers, photographers) are being aware of 'strange-looking' species thanks to field-guides. We cannot say that the last decade can be seen as is part / start of a trend, because the majority (103) of the new species has been published by Veron (2002) and they are the result of many field trips sponsored by nature conservation organizations or they are material donated to the taxonomist by other scientists. Because of the anticipated synonyms I cannot give a good rationale but only a rough guess. Another problem is that fewer taxonomists will be around to verify whether a newly collected strange-looking coral is a real new discovery.

Cryptic

0–142. My guess is that the number of cryptic scleractinian species to be discovered through molecular analyses is practically zero. It is still difficult to get markers that work at species level (for some families easier than for others). If we do have them, we use them for phylogenetic research mostly. Deep sea corals are difficult to obtain for molecular research (counting appr. 50% of the total). I do not expect that we find sibling species easily. Mostly we check for species by molecular support if we find morphological indications.

In contrast to Bert Hoeksema's view, Stephen believes that for the deep water coral species, this is 20% of the known deep water species: $0.2 \times 711 =$ about 142.

<p>Cubozoa [Allen Collins]</p>	<p>Described 37 species.</p> <p>Nominal 46 species names. These numbers come from recent updates I have made to</p>

	<p>the cubozoan entries in WoRMS. There might be a couple of other nominal species, but this should be quite close to correct (at present).</p> <p>Undescribed, collected I am aware of 9 additional species of cubozoans, whose descriptions are in progress (3 as part of submitted manuscripts), as well as one case where a nominal species will be synonymized. I would think that 10–20 would serve the purposes of our analyses.</p> <p>Undiscovered This is quite difficult to estimate, but I would not be surprised if we have perhaps 20–50 additional species to discover in this group. This would be my guess, but it is not based on any sort of analysis.</p>
<p>Hydrozoa [Peter Schuchert]</p>	<p>Described 3,521 marine species (Schuchert, 2011).</p> <p>Nominal Unaccepted species of Hydrozoa in WoRMS (1,000) multiplied with about 1.5 (very rough estimate!).</p> <p>Undescribed, collected This is almost impossible to say as it is not known what collection are available, though not many I guess, new species are more likely discovered by studying living material (esp. in medusae). I guess 50–100 species.</p> <p>Undiscovered Difficult to answer, see my paper of 1998, my feeling is that about 20% more are to be discovered based on morphology, many more with molecular methods (perhaps 100%) ⇒ morphospecies to be discovered: 500–1500 species.</p> <p>Cryptic ⇒ 1000–2500 species.</p> <p>References Schuchert, P. (2011). World Hydrozoa database. Available online at http://www.marinespecies.org/hydrozoa. Consulted on 2012–01–12 Schuchert, P. (1998). How many hydrozoan species are there? Zool. Verh. Leiden 323, 209–219.</p>
<p>Siphonophorae [Phil Pugh, Gill Mapstone]</p>	<p>Described There are c. 176 valid species of siphonophore, with c. 8 species inquirendae.</p> <p>Nominal The number of synonyms for these species is at least 510, making an average of 3 synonyms per species; but the distribution is very uneven as, for instance, the Portuguese Man O'War, <i>Physalia physalis</i>, has about 50 junior synonyms.</p> <p>Undescribed, collected The number of known but undescribed species lies in the region of 50–60.</p> <p>Undiscovered</p>

	<p>Between the 1810s and the 1990s the increase in new species descriptions is almost linear, but in the last decade there has been an upturn, which probably will continue as the c. 50 known new species are described. We would estimate that the number of as yet undiscovered species lies within a similar range. The average number of species described per year, since 1758 is 0.68 (max 12 min 0), or 6.8 per decade (max 20 min 0).</p> <p>Many, but not all, of the early researchers used dip nets or buckets to collect their material from superficial waters, so that before 1900 4 cystonect, 22 physonect, and 35 calyphoran species had been described. However, most of the 20th century authorities relied on material collected by nets. Because of their fragility, and the fact that they are comprised of a myriad number of individuals, physonect siphonophores are often destroyed by or extruded through the netting, and the pieces that remain are often difficult to identify. Many calyphoran species, however, have relatively small nectophores that are fairly robust, and each colony is comprised of only one or two of them, and in the latter case they have different morphologies. These differences between the physonects and calyphorans are exemplified in the breakdown of the 73 siphonophore species described between 1900 and 1982; 1 cystonect, 19 physonects, and 54 calyphorans.</p> <p>With the advent of in situ collecting methods, SCUBA, submersibles, ROVs it was now possible to collect complete specimens of the fragile physonect species; while on the other hand the collection of the smaller calyphoran species depended greatly on the visual acuity of the collector. Thus, particularly in deeper waters, one tends to observe more physonect specimens than calyphorans, and this is, again, reflected in the number of new species described in recent years, namely 21 physonects and 17 calyphorans.</p> <p>The fact that, with an increasing rate of publication of descriptions of new siphonophore species, 80% of the estimated number of known but undescribed species is physonects indicates that we have only just begun to appreciate the significance of this group of siphonophores. It should also be noted that the deeper living populations of siphonophores have only been investigated, using in situ techniques, in a limited number of areas. In our case this is The Bahamas, the Cape Cod region, and Monterey Bay. In addition Dhugal Lindsay has been investigating the seas around Japan.</p> <p>Cryptic As far as we are aware there are no cryptic species.</p>
<p>Scyphozoa [Michael N Dawson, Liza Gómez-Daglio]</p>	<p>Described 201 accepted described marine species. Based on the summary of species listed on The Scyphozoan website (archived ca. 2007) appended with more recent species descriptions found by querying the Zoological Record database for TITLEsearch “Scyphozoa AND new AND species” ==> zero additional TITLEsearch “jellyfish* AND new AND species” ==> zero additional TITLEsearch “Scyphozoa AND sp. AND nov.” ==> 1 additional TITLEsearch “jellyfish* AND new” ==> 1 additional, 1 cryptic TITLEsearch “scyphozoa* AND new” ==> 4 additional ANYWHEREsearch “scyphozoa* AND new AND species” ==> 0 Also appended with one publication not yet in ZR.</p>

Nominal

204 nominal marine species.

Preliminary molecular analyses suggest *Phyllorhiza peronleseuri* is same as *P. punctata*. Morandini & Marques (2010) – suggest several nomen dubium, species inquirenda from Gershwin & Zeidler (2008).

Undescribed, collected

= (a) 80, to (b) 38

(a) We calculated the number of taxa in published papers that were not identified to species but were stated in the publication as being a distinct taxon or awaiting description (*e.g.*, Gershwin 2003; Holland *et al.*, 2004; Dawson *et al.*, 2005; Bayha & Dawson 2010; Bayha *et al.*, 2010; and taxa listed as “sp.” in Kramp (1961) and Segura-Puertas (1984, 2003) [N.B. spp. classed as single sp.]).

(b) Enumerated lots that are identified (and unidentified) in several natural history collections (CAS, CRRF, MCZ, NMNH, ZMB). Enumerated identified species. From these numbers we estimate how many species may be in the unidentified lots assuming new species are randomly distributed among all lots, but that lots from the same region and time likely contained similar medusae. N.B. We consider this likely an overestimate because the most interesting lots will have been worked on first, leaving replicates, poorly preserved specimens, etc as the majority of unidentified lots, especially in well-visited museums. More obscure collections may have higher proportions of undescribed species.

To try to offset the potential overestimate by counting lots, we asked Allen Collins to look in SI collection for unidentified lots earmarked for description of new species by one person or another. Allen returned his best estimate as 3 (three) undescribed species compared with 91 described species at NMNH, *i.e.*, 96.7% of species in collections are described (from a well-known, well-visited museum).

These six estimates were averaged (19%) and multiplied by the accepted current number of described species to give our estimate of 38 undescribed species in collections.

Undiscovered

77 undiscovered marine species not yet collected.

In the last two years, Liza has conducted extensive collections from Mexico to Panama, a previously moderately-to-poorly studied region. Segura-Puertas (1984) and Segura-Puertas *et al.* (2003, 2010) recorded 6 species of scyphozoan from the Tropical Eastern Pacific and Alvariño (1969) reported *Stomolophus* from Gulf of California. Liza found 14 species (excluding 2 invasives) of which 7 are previously unknown records and likely species. This indicates in moderately sampled regions currently described species may represent ~50% of all species present. Assuming fewer species (tending toward zero) remain to be found in well-sampled regions, and more species remain to be found in poorly-sampled regions (tending toward 65%), and that these regions are more-or-less evenly sized and distributed around the world w.r.t. biodiversity, we use 38% as our estimate of the number of species remaining to be collected.

Cryptic

Our estimated percentage of morphospecies that are cryptic is 7%.

This figure was calculated as (number of taxa known to be highly divergent on the basis of only molecular data) / (number of valid species) * 100, and does include multiple cryptic species within a single morphospecies in some cases. This means we'd expect to find an additional 7% * 316–358 cryptic taxa (bringing the total count to 338–383 species of scyphozoans). We do think the 7% figure is a little low, but our guesstimate developed over the years was that the number of scyphozoan species might double (*i.e.*, to ~400; *e.g.*, Dawson 2004; Hamner & Dawson 2009), so we were reasonably comfortable with these numbers calculated various ways. Please also note that the estimated percentage of morphospecies that are cryptic (7%) is much less than the number of species that we expect will be discovered by applying molecular techniques. This is because by focusing on species that are morphologically different, we've shunted a good proportion of species that were originally discovered using genetics and subsequently distinguished morphometrically from the "cryptic" to the "undescribed" categories. Ultimately, the total estimate of species richness is about the same, but the way we get there different.

<p>Staurozoa [Claudia Mills, Allen Collins]</p>	<p>Described Total described: 48 species</p> <p>Nominal 63 (as reflected in recent updates to WoRMS).</p> <p>Undescribed, collected Min-max: 10–12 species.</p> <p>Undiscovered Min-max: 30–50 species. It seems to me a fair estimate of undiscovered Stauromedusae is to double the present "about 50" to about 100 to be expected in the course of science as we know it. Certainly the last decade has indicated that new Stauromedusae just aren't that hard to find yet.</p> <p>Cryptic Min-max: 0–3 based on preliminary data from six species showing no indication for any cryptic species.</p>
<p>Ctenophora [Claudia Mills, Allen Collins]</p>	<p>Described 190, although I doubt if they are all good, but no one has revisited most of the described species.</p> <p>Nominal ~250 (255 including fossil species).</p> <p>Undescribed, collected Min-max undescribed: 25–50. Those of us who know the deep sea undescribed species continue to talk about writing descriptions, but we haven't done any yet. Steve Haddock is doing a molecular phylogeny as he gets the opportunity — many of his "species" for this phylogeny are undescribed. There remain perhaps one-third of the described species (a wild guess) that we don't know whether or not they are real and I've seen a manuscript this week that will extinguish one of those. Ctenophore taxonomy is not a very active field, although there are a few of us on the sidelines thinking about it.</p> <p>Undiscovered The amount of open ocean that has been searched amounts to some small "pencil lines" of transects, and we continue to easily find undescribed</p>

	<p>species. So I would ballpark the estimate of undiscovered new species of Ctenophores, as I did with the Stauromedusae, as about double what we know now, which translates to about 100–250 undiscovered morphospecies.</p> <p>Cryptic Min-max cryptic: 0–10 species (a wild guess that it is low).</p>
Cycliophora [Reinhardt Møbjerg Kristensen]	<p>Described 2 species.</p> <p>Nominal 2 species.</p> <p>Undescribed, collected 3 species.</p> <p>Undiscovered 10–125 if all clawed lobsters have Cycliophora?</p>
Asteroidea [Christopher Mah]	<p>Described 1,922 species (based on WoRMS). I find this pretty reasonable</p> <p>Nominal 5,549 species (based on WoRMS).</p> <p>Undescribed, collected Based on my museum sampling over the last few years approximately 125–200 specimens are undescribed new species. Especially in the Goniasteridae.</p> <p>Undiscovered 20–25% of Goniasteridae species were described in the last 10 years. 25% of the genus level diversity. Based on this and estimates from the new species in collections, approximately 10 to 25% may remain to be discovered. This estimate is much higher if you factor in considerations of cryptic species uncovered by DNA population studies. The monotypic <i>Acanthaster planci</i> has been interpreted as being composed of up to 3 or 4 species based on recent phylogeography studies. Other widely discovered taxa may show similar hidden diversity.</p>
Echinoidea [Andreas Kroh, Rich Mooi]	<p>Described 999 valid extant species (Kroh & Mooi, 2011). Estimating the number of known echinoid species was relatively straightforward, it is based on the number of species considered valid by Mortensen (1928–1950), plus those described after completion of the last volume of his Monograph. The latter were based on data taken from Kier & Lawson (1978) for period of 1951–1970, and Kroh (2010) for the years 1971–2008. Additionally, online and offline resources were scanned for extant echinoid species described in 2009 and 2010. For the purpose of the present estimate, subspecies were excluded, thus possibly underestimating true echinoid biodiversity. An up-to-date classification of the Echinoidea and a list of currently accepted genera can be found in Kroh & Smith (2010).</p> <p>Nominal Currently 1598 extant nominal echinoid taxa (accepted + unaccepted) are</p>

recorded in our database (Kroh & Mooi, 2011). Although additional disused 19th century species continue to be occasionally found, most are now included. Please note that this differs from the number of different names under which echinoids have been cited (*i.e.*, different combinations), which amount to about 3,000 names.

Undescribed, collected

This may range from 20 to 50. Based on a survey of a number of recent papers describing new extant echinoid taxa, it seems likely that up to 30 % of the taxa yet to be described are already present in the collections.

Undiscovered

This may range from 45 to 150. To estimate the number of species yet to be discovered is fraught with difficulties. Here the discovery rate of extant echinoid species during the last 60 years was calculated by polling the number of species established in each decade and comparing subsequent decades with each other. This results in a mean discovery rate of 0.92, indicating that a lot of extant echinoids are still being discovered. Using this rate to model future taxon discovery results in 110 species of extant echinoids still to be discovered, 90% of which are expected to be described till the year 2250. It has to be cautioned, however, that the variance of the discovery rate during the last 60 years is high for extant echinoids and that these figures are only crude estimates. Additionally, being a small group, both in terms of species and research community, any intense single person effort is bound to drastically affect future discovery rates, much like Mortensen's work on the Monograph of Echinoidea (1928–51) strongly increased discovery rates and accounted for about 60 % of all newly discovered species during that period. Mortensen alone described about one fifth of all accepted extant echinoid species.

Cryptic species

Investigation on this issue is just starting in echinoids and the estimates presented below thus poorly constrained. About a third of the extant echinoid species examined hold complexes (pers. comm. Gustav Paulay, 24.1.2011). In the studies on *Echinometra*, the only taxon investigated in relation to cryptic speciation in echinoids, three cryptic species were discovered, out of 8 morpho-species in that taxon.

Based on this I would estimate importance of cryptic speciation as low to moderate in echinoids, *i.e.*, 1 to 3 cryptic species per morph-species holding species complexes.

Calculation used to estimate number of cryptic species:

Min. cryptic species = 1135 (min. morpho-species) * 0.3 (percentage of echinoid species supposed to harbor complexes) * 1 (min. est. no. of cryptic species per morph-species holding species complexes) = 306

Max. cryptic species = 1270 (max. morpho-species) * 0.3 (percentage of echinoid species supposed to harbor complexes) * 3 (max. est. no. of cryptic species per morph-species holding species complexes) = 1,080

(Basis: No. of morpho-species (min-max): 1020–1200 [known + unknown])

<p>Ophiuroidea [Sabine Stöhr]</p>	<p>Described 2,064 species (Stöhr, O'Hara & Thuy, 2012).</p> <p>Nominal >3,100 species names (Stöhr & O'Hara, 2011).</p> <p>Undescribed, collected 260–300 species have been putatively identified as undescribed by the leading experts.</p> <p>Undiscovered 200–400 species. The rate of species descriptions has been about 10 per year in the last decade, compared to twice that many during the most prolific time (1870–1940) of ophiuroid description. Description rates do however not decrease linearly over time as the number of species to discover declines. They also strongly depend on opportunity and personal interest of the respective researchers. In addition, species definitions change over time and any estimate of undiscovered species numbers can only be an indication of magnitude, rather than absolute numbers.</p> <p>Cryptic</p>

	<p>100–150. My estimate may be more conservative than what geneticists expect. Ophiuroids are less well studied than echinoids, with currently a small fraction of the number of sequences in GenBank than there are for echinoids. Published and still undergoing genetic studies suggest that some species are complexes of two or more species (Boissin <i>et al.</i>, 2011). However, there may be a selection bias, because certain groups are much more variable and difficult to understand than others and molecular studies tend to focus on these. Extrapolating from those groups will overestimate diversity. There is also a problem with definitions of cryptic species. Often, morphological (and other) differences are recognized when molecular data indicate separate lineages in a morpho-species, resulting in the delimitation of two morpho-species (Stöhr & Muths, 2010). These are then no longer cryptic and probably never where, just understudied and unrecognized. Therefore the terms undiscovered and cryptic species overlap and should be viewed together.</p> <p>References Boissin, E., Stöhr, S., and Chenuil, A. (2011). Did vicariance and adaptation drive cryptic speciation and evolution of brooding in <i>Ophioderma longicauda</i> (Echinodermata: Ophiuroidea), a common Atlanto-Mediterranean ophiuroid? <i>Molecular Ecology</i> 22, 4737–4755. Stöhr, S., and Muths, D. (2010). Global diversity of brittle stars (Echinodermata: Ophiuroidea). <i>PLoS ONE</i> 7, e31940. doi:10.1371/journal.pone.0031940.</p>
<p>Crinoidea [Charles Messing]</p>	<p>Described My best estimate of the number of living crinoids is 623, although I expect quite a number to be synonymized and at least a few to be separated from within named taxa.</p> <p>Nominal I estimate around 300 synonyms exist (not including nomina nuda and misspellings).</p> <p>Undescribed, collected I currently have 5 undescribed species in my possession, but I have no good idea what might be lying about in museum collections (especially in Paris).</p> <p>Undiscovered I expect between at least 50 and 100 crinoid species remain to be discovered. New species and genera continue to be found on a regular basis, particularly from deep water. The known crinoid fauna of the tropical western Atlantic numbers approximately 55 species (the status of a few subspecies remains uncertain), with the great majority described before 1950. However, during a 10-day submersible cruise to the Bahamas in 2009, I found what appear to be four new crinoid species chiefly in ~600 m depth, which increases the regional fauna by 7%.</p>
<p>Holothuroidea</p>	<p>Described</p>

<p>[Gustav Paulay]</p>	<p>Number of accepted species: Bit fuzzy, as synonymies vary and some are old. In the database I have there are ~1710–1740 accepted names depending on how you cut it (and considering some unchecked things). I suspect this is an overestimate and once I trace the fate of a number of these the real number will be closer to 1,600. Data from WoRMS: 1,683 valid marine holothuroid species.</p> <p>Nominal 2,347 available names at present and this is probably pretty close. Does not include nomina nuda, suppressed names, or any not-available name.</p> <p>Undescribed, collected No good estimate possible. Cryptic species are a huge issue, collections are full of them, but they need to be tested genetically as often there are no discernible morphological differences in preserved specimens. This is presently difficult at best for old specimens. In terms of morphologically recognizable species, I would guess about 200–400 are in collections, but I have not seen some of the largest collections, so this is a bit of a wild guess.</p> <p>Undiscovered We are finding cryptic species to be a huge issue, especially in deep sea material. I would guess at least as many species remain undiscovered as have been described, but this estimate is very poorly constrained.</p>
<p>Echiura [John Pilger]</p>	<p>Described Presently the number of described and accepted echiuran morphospecies is 175. However, many descriptions are incomplete or ambiguous so the number could vary considerably after a thorough review of types.</p> <p>Nominal I estimate 29 synonyms and 7 as <i>incertae sedis</i>.</p> <p>Undescribed, collected Based on my personal collection and discussions with others I estimate that there are 5–10 collected but undescribed species.</p> <p>Undiscovered I estimate that roughly 70–80% of the species have discovered. Based on the number of described and accepted species, 175, there could be 35–50 species that are undiscovered. In the past, when there were more people studying echiurans, specific collecting expeditions were conducted. More recently echiurans are discovered incidental to regional and site-specific benthic surveys.</p>
<p>Entoprocta [Claus Nielsen, Tohru Iseto]</p>	<p>Described There are 143 valid names in the Loxosomatidae. Colonial forms: about 50 valid names.</p> <p>Nominal About 5 Loxosomatidae are synonyms and about half of the colonial forms are probably synonyms.</p> <p>Undescribed, collected Tohru has about 30 undescribed species in his collection.</p>

	<p>Undiscovered Our conservative guess is 1,000 undiscovered species (but the number may well be higher).</p> <p>Cryptic There is no evidence (no basis for judgment) for cryptic speciation in the Entoprocta.</p>
<p>Gastrotricha [Antonio Todaro; William Hummon</p>	<p>Undescribed, collected About 310 (this number includes information from Antonio Todaro (96 spp), William Hummon (180 spp) and other 5 colleagues active on marine Gastrotricha (collectively 36 spp).</p> <p>Undiscovered These estimates (based on morphology) come out considering: a) several new species are still found in areas quite well sampled (Mediterranean-Italy and northern Europe); b) 200 undescribed species are known from areas that have barely been sampled: Middle Atlantic, Hawaii, North Carolina, New England, the Pacific Coast of US and the Middle East. In this areas the number of present species can be doubled easily <i>e.g.</i>, sampling different habitats; c) there are many other places on the earth that have not been sampled at all. From my experience (Brazil and Kuwait) 80% of species collected in new areas are new to science.</p> <p>Cryptic Cryptic genetic diversity (in known species) may range from 56 to 81%. These last estimates come from the following reasoning: (1) so far there are only two studies in this regard, both carried out by me and co-workers. (2) The first study (based on the mitochondrial COI and RFLPs analysis) indicated that 3 populations of the transatlantic <i>Xenotrichula intermedia</i> may in fact be four cryptic species.</p> <p>The other very recent study, based on comparisons of sequences of the mitochondrial COI, indicated that four putative populations of <i>Turbanella cornuta</i> from the North Sea, Tyrrhenian sea, Adriatic sea and Persian Gulf are in fact four different species (p-distance: intrapopulation < 2%, inter-population >15%).</p> <p>The take home message from these studies is: species known to have a wide geographic range are in fact species complexes; the number of species of these complexes varies depending on taxon and amplitude of its putative range.</p> <p>Considering that about 15–20% of the known marine gastrotrich species are anphiatlantic and/or regional cosmopolitans, and estimating that each of these taxa may be composed in average of 4 species (a different species for each basin) we'll get the following number of cryptic species added to the total unknown figure: $1,310 * 0.15 * 3 = \sim 500$ $1,810 * 0.20 * 3 = \sim 1,000$</p> <p>References Todaro, M.A., Fleeger, J.W., Hu, Y.P., Hrinkevich, A.W., and Foltz, D.W. (1996). Are meiofauna species cosmopolitan? Morphological and molecular analysis of <i>Xenotrichula intermedia</i> (Gastrotricha:</p>

Gnathostomulida [Wolfgang Sterrer]	<p>Described 98 species (latest addition by Sterrer 2011).</p> <p>Nominal 98+11=109 species names.</p> <p>Undescribed, collected 15–20 species.</p> <p>Undiscovered 200 species. Over the past decade, my collecting (Sterrer, in prep.) on Indo-Pacific coasts (from S. Africa to Red Sea, Hong Kong, Japan, NW America and Galapagos) will bring the total number of species known from the Indo-Pacific from 38 to 74 species, including 18 species new to science.</p> <p>Cryptic No basis for judgement.</p> <p>References Sterrer, W. (2011). Two species (one new) of Gnathostomulida (Bursovaginoidea: Conophoralia) from Barbados. <i>Proc. Biol. Soc. Washington</i> 124, 141–146.</p>
Hemichordata [Billie Swalla, Noa Shenkar, Chris Cameron]	<p>Described The final number of Hemichordate species described now is 118 species. However, this number represents only a small portion of the true richness of hemichordate species, and reflects the low sampling effort invested in this group (Cannon <i>et al.</i>, 2009). The number of undiscovered and undescribed species is high, probably at least 500, if not over 1,000. Recent deep sea expeditions have found a number of new species in the recently described family Torquaratoridae (Osborn <i>et al.</i>, 2011) and many more species are being described from the extensive Bullock collections by Chris Cameron and colleagues (Cameron <i>et al.</i>, 2010; Deland <i>et al.</i>, 2010).</p> <p>Interesting points from mapping the biogeography of hemichordates: 1) The striking low numbers of hemichordates from tropical waters, an environment that represents the highest marine biodiversity suggest that many new species remain to be discovered, and 2) The high number of species described based on a single specimen and a single site.</p> <p>Nominal In the Hemichordata there are only few cases of synonymy in comparison to other marine groups (less than %10). More cases of synonym may be revealed in the future by combining molecular methods with classic morphological parameters (<i>e.g.</i>, the case of <i>Saccoglossus kowalevskii</i> and <i>S. bromophenolosus</i>, King <i>et al.</i>, 1994).</p> <p>Undescribed, collected Dr. Chris Cameron from the University of Montreal in Canada is describing the extensive enteropneust collection from the deceased Dr. Theodore</p>

	<p>Bullock at Scripps Institute (Cameron <i>et al.</i>, 2010; Deland <i>et al.</i>, 2010). Osborn <i>et al.</i> (2011) described 4 new genera (A-D) of the deep sea family Torquaratoridae, that is a sister clade to the Ptychoderidae. They also reported 18 undescribed enteropneust species from their recent expeditions, suggesting that there is a large diversity of deep sea hemichordates. Noa Shenkar reports a collection stored at the National Collections of Natural History at Tel Aviv University, Israel. This collection includes a wide variety of samples from different Red Sea expeditions and Mediterranean coasts surveys. The few hemichordate specimens (<10 jars) are not identified to species levels. Dr. Billie Swalla at the University of Washington has a collection of several undescribed enteropneust worms and also a collection of tornaria larvae that are being sequenced and described morphologically.</p> <p>References Cameron, C., Deland, C., and Bullock, T. <p>Mesozoa (Orthonectida, Dicyemida) [Hidetaka Furuya]</p>	<p>Described 134, data based on WoRMS</p> <p>Nominal Only 1%.</p> <p>Undescribed, collected We have at least 40 and maximum 50 undescribed species in our collections now.</p> <p>Undiscovered Roughly estimated, there are at least 1,000, maximum 1,500 species in total. In Japanese waters, we may find the maximum of 100 species. Similar waters are counted from 10 to 15 in the world.</p> <p>Cryptic May count for 100–500 species.</p>
<p>Bivalvia</p>	<p>Described</p>

<p>[Gary Rosenberg]</p>	<p>At the moment WoRMS has 8,081 accepted species of bivalves. From this should be subtracted 27 fossil only and 35 freshwater only, and at least 100 duplicates (judging from remaining non-checked items that have Chemnitz as author or lack authority altogether). So we take 7,900 valid species in WoRMS as the basis for estimating number of bivalve species.</p> <p>Regarding how many Tellinidae and Galeommatidae are missing: galeommatids comprise 11.5% of the New Caledonian bivalve fauna in Bouchet <i>et al.</i> (2002) and tellinids 9.8%. The ratio of those two groups to other bivalves is $111/408 = 27\%$. WoRMS already has 301 accepted tellinids and 409 accepted galeommatoids. If we subtract those from 7,900 we get about 7,200 bivalve species. If we then add 27%, we get an estimate of 9,144 species. However, the New Caledonia figures include undescribed species, which for galeommatoids in particular biases the result to be too high.</p> <p>In the Japanese fauna, based on Higo, Callomon & Goto (1999), galeommatoids are 4.8% and tellinids 6.7%, or $168/1304 = 13\%$. This gives an estimate of 8,136 species. In the Eastern Pacific fauna using Keen 1971 gives $116/676 = 17\%$, which estimates 8,424 species. If we allow for a generous 10% missing in the latter figure, the estimate would be 9,266. Given the uncertainties involved, the estimate should have only one significant digit, so the choice is between 9,000 or 10,000. The evidence we have suggests that 9,000 is closer to the mark.</p> <p>Reference Bouchet, P., Lozouet, P., Maestrati, P., and Heros, V. (2002). Assessing the magnitude of species richness in tropical marine environments: exceptionally high numbers of molluscs at a New Caledonia site. <i>Biol. J. Linn. Soc.</i> 75, 421–436. Higo, S., Callomon, P., and Goto, Y. (1999). Catalogue and Bibliography of the Marine Shell-bearing. <i>Mollusca of Japan</i>. 749 pp.</p>
<p>Caudofoveata [Oscar Garcia-Alvarez, Philippe Bouchet]</p>	<p>Described 133 species (data in WoRMS).</p> <p>Nominal 145 species (data in WoRMS).</p> <p>Undescribed, collected We have 5 unstudied new species. It is difficult to say but at least another 10–15 more species (Philippe Bouchet prefers to put a question mark).</p> <p>Undiscovered Oscar believes approximately 65% is still not known of Caudofoveata. However, Philippe estimates 500 undiscovered spp.</p>
<p>Gastropoda [Serge Gofas, Gary]</p>	<p>Described A complete list of gastropod species is not yet available, and estimates are</p>

Rosenberg]	<p>based on a gastropod/bivalve ratio. In Bouchet <i>et al.</i> (2002), the ratio was found to be 4.2:1. With 9,000 bivalves, there would be 37,800 gastropods. For estimates for all taxa, it would probably better to give a range than a single number, <i>e.g.</i>, 36,000 +/- 4,000.</p> <p>Note that there are thousands of names listed as valid even though no one has studied them for 100 years. Many of them could have been marked as species inquirenda.</p> <p>Undiscovered Based on the following "hard" data:</p> <ul style="list-style-type: none"> • Bouchet, Heros, Lozouet & Maestrati (2008): All deep-water papers in the MNHN cruises, 743 new species representing half of total studied (in "large" families <i>e.g.</i>, Muricidae, Tonnoideans...) • Peñas & Rolán (2010): Pyramidellidae (Turbonillini) 239 identified species, 209 new to science (87%) in a size range < 10 mm • Peñas & Rolán (submitted): Pyramidellidae (Chrysallidini) 235 identified species, 214 new to science (91%) in a size range < 10 mm • Bouchet, Heros, Lozouet & Maestrati (2002): 51,91% (about half) of species are less than 8.7 mm so same size-range as Pyramidellidae (their figure 4). <p>This can be extrapolated to some extent. To be refined, we would need to know the ratio of "deep" versus shelf/shore species but to start with we could assume equivalent numbers. We also have to assume that the size ratios nearshore are equivalent to those in the deep. Next, to assume that the ratio of undescribed depends on size. Then, considering 40,000 known Gastropods, this would give:</p> <p>In the "deep" realm: 20,000 known species of which 10,000 "large" known by 50% and 10,000 "small" known by 10% so (20,000 total known + 10,000 unknown "large" + 90,000 unknown "small"): total estimated 120,000. In the "shallow" realm, the "unknown number could be anything between 0 and 50% so the most conservative estimate (assuming everything known) would give 120,000 to 140,000 gastropod species overall.</p> <p>References Bouchet, P., Lozouet, P., Maestrati, P., and Heros, V. (2002). Assessing the magnitude of species richness in tropical marine environments: exceptionally high numbers of molluscs at a New Caledonia site <i>Biol. J. Linn. Soc.</i> 75, 421–436. <p>Polyplacophora [Enrico Schwabe]</p>	<p>Described Should be 930.</p> <p>Nominal c. 1,950.</p> <p>Undescribed, collected I may only estimate this roughly from what I saw. It's difficult as I do not know all institutions. I guess there might be additional 50 species (also taken species into account, which occur in my database as Genus sp.)</p> <p>Undiscovered This is even more difficult, as usually no quantitative sampling efforts were undertaken to collect chitons. Fact is that intensive collection in different regions (even well examined) often yield new species, but depending on the environment the number may differ considerably. Unexplored deep-water regions may provide a higher number, than shallow water regions. Having a quick look on what was ongoing during the last decade, I guess we speak also of about 50–100 new species, but as explained before is more a belly-feeling rather a statistic base.</p>
<p>Scaphopoda [Victor Scarabino]</p>	<p>Described 572 species (data: WoRMS up to 2012–1–20, http://www.marinespecies.org/aphia.php?p=taxdetails&id=104)</p> <p>Nominal Steiner & Kabat (2004) consider 517 (recent) valid species, 311 synonyms and other combinations. Studies carried on after 2004 (2, 3, 4, 5, 6, 7, 8) new combinations and synonyms were submitted, and 63 new spp. were described, reaching to 572 valid species.</p> <p>Undescribed, collected 55 species, most at the care in the collections of the MNHN and in the NMNH are identified as new (12 Dentaliida and Gadilida 43, (VS mid-2011).</p> <p>Undiscovered Even that sounds ambitious, in my opinion, 500 species is a coherent number. This assumption is based on the lack of updated records from large ocean areas, such as the western and central Indian Ocean, the tropical eastern Pacific and in deep-water realms around the world (most of the Scaphopoda distributes in the slope to abyssal environments, ± 66%, based on live records confirmed in several institutional collections (VS pers obs).</p> <p>Cryptic I prefer to state "no evidence / lack of information." Evidence could be available after processing of materials ready for barcode studies (mainly at the care of MNHN).</p>

<p>Solenogastres [Oscar Garcia-Alvarez]</p>	<p>Described 263 species (7 with doubts).</p> <p>Nominal 335 species names (263 accepted species + 72 synonyms).</p> <p>Undescribed, collected I know directly 18 species; it is difficult to say but at least another 20–30 more species.</p> <p>Undiscovered If we suppose, as is indicated in the literature, that still around 60% of the diversity in solenogastres is not known, than we would have 320–480 species unknown.</p>
<p>Myxozoa [Stephen W. Feist, Matt Longshaw]</p>	<p>Described The most recent review of myxozoan genera was compiled by Lom & Dyková (2006). To that date a total of 2,180 myxosporean species, belonging to 62 genera were recognized. Of these 37 genera were regarded as exclusively marine with a further 8 genera containing species infecting marine and freshwater fish species, the remainder being exclusively freshwater. Since 2006, several new myxosporean genera have been erected following the discovery of previously undescribed species (at least 4) but each genus contains only the single type species. The current estimated</p>

	<p>number of described marine myxosporeans is 700.</p> <p>Nominal For several myxosporean genera, for example <i>Myxobolus</i> (approximately 800 species reported in the literature), there is increasing evidence of widespread synonymy between species. For this predominantly freshwater genus this appears to be particularly prevalent but there have been insufficient molecular studies to confirm. However, most genera of marine myxosporeans contain fewer than 60 species with several genera containing a single type species. Including synonyms it is estimated that there are approximately 750 marine myxosporeans.</p> <p>Undescribed, collected There are few collections of marine myxosporeans awaiting descriptions although several researchers around the world will have obtained material of a few species. Estimates for these based on contacts from scientific networks such as http://www.myxozoa.org/ suggest that there are relatively few undescribed species already collected, perhaps fewer than 100 with a maximum of 250.</p> <p>Undiscovered The number of undiscovered species is certain to be substantial. Only a small percentage of the available hosts, <i>i.e.</i>, all fish species and potentially marine reptiles, have been investigated and many geographic areas such as the polar regions, deep sea environments, Middle East are practically uninvestigated for myxosporean species. It is reasonable to suggest that on the basis of numbers of fish hosts alone at least 30–40% are likely to harbor species new to science. This could equate to between 6,300 to 8,400 species (assuming 21,000 known and unknown marine fish species).</p> <p>Cryptic As for ‘cryptic diversity’, we estimate this as being low, between 1 and 5%.</p> <p>References Lom, J., and Dyková, I. (2006). Myxozoan genera: definition and notes on taxonomy, life-cycle terminology and pathogenic species. <i>Folia Parasitologica</i> 53, 1–36.</p>
<p>Nematoda (free-living) [Jan Vanaverbeke]</p>	<p>Described & nominal 6,900 and 710 synonyms based on NeMYS (Deprez <i>et al.</i>, 2005).</p> <p>Undescribed, collected Unknown.</p> <p>Undiscovered The most recent estimates of marine nematode species numbers vary between 10,000–20,000 species (Mokievsky & Azovsky, 2002) and 10⁵ – 10⁶ (Lamshead & Boucher, 2003). The method in Mokievsky & Azovsky (2002) is a rough calculation based on extrapolating alpha-diversity within relatively small plots (by species-specimen relations or rarefaction procedures), taking into account the effects of area, biotope and historical-geographical processes). Lamshead & Boucher’s (2003) estimate is based on 21 cores of five stations along a N-S transect in the Pacific. When the species-accumulation curve up from north to south, they come to 10 million, and from south to north to 100, 000. This is caused by a productivity</p>

	<p>gradient, which affects the shape of the curve. In addition, Lamshead & Boucher (2003) mention that about 30–40% of the nematode species encountered in European waters are new to science. On the very well studied Belgian Part of the North Sea (surface: 3600 km², 74 sampling stations), 443 species were identified and 52 new species were recorded. (Vanaverbeke, pers. comm.). In less investigated coastal areas, the amount of undiscovered species is even higher. In a recently finished PhD on Vietnamese mangrove systems, Nguyen (2009) found 115 species; about 40% could not be fully identified and are probably new to science. In Cuban coastal waters, a recent survey resulted in 4 nematode genera new to science, on a total of about 80 genera recorded during the survey (Armenteros, 2009). In addition to this, it is well accepted that nematode diversity in the deep sea is far from known due to lack of basic taxonomic studies (Fonseca <i>et al.</i>, 2006).</p> <p>In conclusion, 10–20,000 seems too conservative, and >1,000,000 too high. Considering the high dispersal and survival of nematodes in poor conditions, 50,000 could well be right. Anyway, all this suggests that the actual number of described free-living marine species does not at all cover the amount of species that can be encountered in marine sediments.</p> <p>Cryptic Besides Derycke <i>et al.</i> (2008) almost nothing is known on cryptic diversity in nematodes. This paper discovered many cryptic species in <i>Pelioiditis marina</i> in the Westerscheldt, but it is impossible to scale this up to all the remaining (cosmopolitan) species.</p> <p>References Deprez, T. <i>et al.</i> (2005). Nemertea [Jon Norenburg]	<p>Described 1,275 species as of Kajihara <i>et al.</i> (2008). About 1,285 now.</p> <p>Nominal</p>

	<p>My best estimate is 1,600 marine species (actual count is 1,604 but the margin of error could be as much as 25, or more).</p> <p>Undescribed, collected Min-max: 200/400.</p> <p>Undiscovered Min-max: 500/1000.</p> <p>References Kajihara, H., Chernyshev, A.V., Sun, S.-C., Sundberg, P., and Crandall, F.B. (2008). Checklist of nemertean genera and species published between 1995 and 2007. <i>Spec. Diver.</i> 13, 245–274.</p>
<p>Phoronida [Christian Emig]</p>	<p>Described 18 species, of which 10 adults and 8 larval species.</p> <p>Nominal 41 species names, of which 25 adults and 16 larval species.</p> <p>Undescribed, collected None.</p> <p>Undiscovered Probably none.</p>
<p>Placozoa [Bernd Schierwater]</p>	<p>Described 1 species.</p> <p>Nominal 1, <i>Trichoplax adhaerens</i> (but see below for different view).</p> <p>Undescribed, collected Genetic data, particularly from the mitochondrial 16S gene (published) as well as from ND1, CO1, and ITS1–2 (unpublished), suggests substantial diversification is present within Placozoa. The number of distinct haplotypes reported for this marker has risen to 18. The relationship between these divergences and species differences is still unknown, primarily due to a lack of documented morphological divergences, but a conservative estimate would be that at least 18 species corresponding to 8 well-supported relatively deeply diverging clades exist within Placozoa. A reasonable estimate for the maximum number of known undescribed species would be 18, the number of distinct 16S haplotypes known. This is because whole genome sequencing and ultra-morphology studies have revealed distinct differences even between the two most closely related known 16S haplotypes. The first identified morphological differences between <i>Trichoplax adhaerens</i> and the closely related haplotype H2 (Guidi <i>et al.</i>, 2010) will soon lead to a description of a second placozoan species. A formerly reported species, <i>Trichoplax reptans</i>, was insufficiently described, never found again and its existence must be doubted.</p> <p>Undiscovered Considerable uncertainty would exist about the total species richness of Placozoa, but Eitel and Schierwater (2010) estimate that the number of 16S haplotypes could total anywhere from several dozen to “in the hundreds”,</p>

	<p>based on the relationship between sampling sites and haplotypes uncovered. Keeping in mind that the relationship between 16S haplotypes and species is still unknown, one might roughly guess that the number of undiscovered species could range anywhere from perhaps 10 to more than 100. Differences between the genomes and the ultrastructures of epithelia cells of the most closely related 16S haplotypes suggest that all currently known haplotypes represent different species. Unfortunately, sharp ecological differences between different haplotypes and clades hinder straightforward culturing and examination of the different lineages and make resolving placozoan systematics a burdensome and slow process.</p> <p>Cryptic For Placozoa all new species are "cryptic species" and they can yet only be identified by genetics.</p> <p>Reference Eitel, M., and Schierwater, B. (2010). The phylogeography of the Placozoa suggests a taxon rich phylum in tropical and subtropical waters. <i>Molecular Ecology</i> 19, 2315–2327.</p>
<p>Monogenea [David Gibson]</p>	<p>These estimates are, judging from the published estimates in local areas, based on the number of fish species still unexamined and the average number of parasites on each examined fish species.</p> <p>Cryptic Any evidence comes from freshwater taxa. On the marine side, lots of new species are currently being described based on minuscule differences in the copulatory and other hardparts. Such work, which usually occurs after genetic differentiation, likely reduces the number cryptic species. So a complete guess on my part would be 500–5,000.</p>
<p>Digenea [Thomas Cribb]</p>	<p>Described There are probably in the vicinity of 6,000 species described. I know of over 4,000 from marine (or brackish) fishes and my records are not complete. So to allow for the species I do not have and those from other host groups (all much less important than fishes), I think 6,000 species would be reasonable.</p> <p>Nominal I would add 1500 species for synonyms.</p> <p>Undescribed, collected Perhaps 600 species.</p> <p>Undiscovered 4000–8500 species. I think that undiscovered species can double the present number. Even well-studied places like the Mediterranean still produce new species regularly and there are still very large numbers in my part of the world.</p> <p>Cryptic 400–900 undiscovered, not collected molecular cryptic species. I think 5–10% cryptic is a reasonable stab in the dark. The problem is not huge, but not insignificant either.</p>
<p>Catenulida</p>	<p>Undiscovered</p>

<p>[Tom Artois, Wolfgang Sterrer]</p>	<p>As to the number of undiscovered species, I think the number given by Wolfgang is realistic. I based myself on a personal communication with Karolina Larsson, who was unable to find a single specimen of marine catenulids during several years of sampling at the Swedish and the Belgian Coast. The number of undiscovered species of Catenulida is probably very few. Wolfgang estimates there are probably 20 species undiscovered.</p>
<p>Rhabditophora (excl. Neodermata) [Tom Artois, Marco Curini-Galletti]</p>	<p>Described Up to now, 2,641 valid species have been described. Counts are based on Tyler <i>et al.</i> (2006–2011) and a comprehensive literature survey.</p> <p>Nominal There are 261 subjective synonyms. The number of nominal species is, therefore, 2,902. The percentage of synonyms is 9%.</p> <p>Undescribed, collected The total number of already collected but yet undescribed rhabditophoran species lies between 500 and 700.</p> <p>Undiscovered For the estimate of the number of undiscovered species, we have used the division of the world's coastal areas into ecoregions as was proposed by Spalding <i>et al.</i> (2007). They recognise 232 ecoregions, and only from 80 of these localities, rhabditophorans are described. This means that species are known from 34% of the regions. In our experience, samplings in new regions, almost always result in a species list with between 80 and 100% of new species. So it is safe to suppose that 90% of the species found in a randomly chosen ecoregion which has never been sampled before is new to science. 2,641 species are known. Therefore, simple calculation leads to an estimate of 4,597 species still to be discovered. However, here we have taken the assumption that in the 80 ecoregions from which flatworm are known, all species that occur there are known (<i>i.e.</i>, that we know the entire turbellarian fauna from that ecoregion). We know this is absurd. Most of these ecoregions are very poorly sampled, most only once or twice, and then mostly only a limited amount of taxa were described (<i>e.g.</i>, only polyclads) and even in many very-well known regions as <i>e.g.</i>, the Western Mediterranean, up to 60% of the species collected are new to science. Furthermore, even in comparatively well known areas, samples have mostly, if not exclusively, been taken in shallow water habitats. The few records from deeper waters, or from marine caves, revealed species not present at shallower depths, casting doubts of the representativity of present, local census of rhabditophoran diversity. Thus, with the exception of the North Sea coast, the Baltic and the Swedish Coast, which are adequately known, for most of the already sampled ecoregions we think an (even conservative) estimate of 75% of undiscovered species in a random sampling campaign is a reasonable estimate. Following this assumption about sampled ecoregions and the 90% rule for unsampled regions explained above, this brings us to an estimate of 28,321 species still to be described, which in our view is much more realistic than the 4,597 species of the first calculation.</p> <p>Cryptic Integrative taxonomy approach, combining morphological, molecular, karyological information, as well as cross-breeding experiments, has recently revealed that genera in the morphologically simple</p>

	<p>Monocelidinae(Proseriata: Monocelididae) include previously undected complexes of cryptic species – as in the cases of the <i>Pseudomonocelis ophiocephala</i> and <i>P. agilis</i> species complexes (Casu & Curini-Galletti, 2006; Casu <i>et al.</i>, 2009). The phenomenon may occur in other taxa of Proseriata, lacking or with ‘simple’ sclerotised structures of the copulatory organ. Such taxa, however, are comparatively few, and most proseriates have complex copulatory structures, which usually aid species discrimination.</p> <p>As to rhabdocoels, data are even less available than in proseriates. In the "species" <i>Gyratrix hermaphroditus</i> real cryptic speciation seems rampant (according to a large amount of molecular data we collected from populations worldwide), although we still have to see to which extent they cannot be distinguished morphologically. For freshwater rhabdocoels, we have (only incomplete) data, that show that the same rule applies as given above: in taxa with few species-level diagnostic characters, there are species that can be identified on molecular grounds only. We, therefore, propose that the number of really cryptic species in Proseriates is limited, less than 1.5 % of morphologically recognised species. Should this be extended to all the other rhabditophorans, it would give a range of cryptic species between 75 and 420 (if the multiplication value is minus or equal to 1.5%).</p> <p>References Casu, M., and Curini-Galletti, M. (2006). <p>Porifera [Rob van Soest, Nicole de Voogd]</p>	<p>Described 8,553 accepted species (mind you, these include those that have not been listed as synonym in any taxonomic study).</p> <p>Nominal 10,967 species names.</p> <p>Undescribed, collected Based on our collections (assuming they are representative of the world's museum collections) we estimate 25–35% undescribed, so that would amount to approx. 2,300–3,000 new species still hiding in the museum collections.</p> <p>Undiscovered An 'old' guess of John Hooper from 1994 is 15,000 species of sponges in world's oceans. We have no reason to adjust this number, but it remains a guess. With on average 50 species described this will be described in 100–150 years.</p> <p>Cryptic</p>

	<p>There are a few studies on cryptic genetic diversity in some widespread Porifera species, but unfortunately the knowledge base is far too small to extrapolate this into an educated guess of overall cryptic diversity in the phylum. I think that naming a figure (<i>e.g.</i>, based on the occurrence of approx. 15% of 'widespread species' you could argue that these are the most likely taxa to contain cryptic diversity and you could arrive in that way at several thousand cryptic species) is not a scientifically responsible action at this moment in time. We need more cases and more elaborate studies of what the genetic clades that appear in the investigated cases really represent: cryptic 'species' are usually based on percentage of sequence diversity observed among investigated individuals and translating these into biological entities that may be recognized morphologically is usually omitted.</p> <p>References Van Soest, R.W.M., Boury-Esnault, N., Vacelet, J., Dohrmann, M., Erpenbeck, D., De Voogd, N.J., Santodomingo, N., Vanhoorne, B., Kelly, M., and Hooper, J.N.A. Global diversity of sponges (Porifera). Submitted to PLoS ONE.</p>
Rotifera [Hendrik Segers]	<p>Described 114 marine and brackish water species (Segers, 2007).</p> <p>Nominal 3,570 species names (Segers <i>et al.</i>, 2012).</p> <p>Undescribed, collected c. 20 species.</p> <p>Undiscovered Undefined. However, cryptic speciation is very important; can amount to a factor 10, see Segers & De Smet (2008).</p> <p>Cryptic My guesstimate of cryptic diversity in rotifers, based on available studies, is between 3 to 20 times that of currently known diversity.</p> <p>References Segers, H. (2007). Annotated checklist of the rotifers (Phylum Rotifera), with notes on nomenclature, taxonomy and distribution. <i>Zootaxa</i> 1564, 104 pp. Segers, H., De Smet, W.H., Fisher, C., Fontaneto, D., Michaloudi, E., Wallace, R.L., and Jersabek, C.D. (2012). Towards a List of Available Names in Zoology, partim Phylum Rotifera. <i>Zootaxa</i> 3179, 61–68. Segers, H., and De Smet, W.H. (2008). Sipuncula [José Ignacio Saiz-Salinas]	<p>Described 150 species (all in WoRMS).</p> <p>Nominal 150 valid + 1,366 synonyms = 1,516 species names.</p>

	<p>Undescribed, collected Very roughly between 3–5 new species. In the period 2000–2010 only 2 new species have been proposed (+ 1 new subspecies). If we take into account the existence of about 5 active taxonomists, we could calculate an average number of 5 new species in a short term of 10 years. Anyway, this last number is quite optimistic in my opinion.</p> <p>Undiscovered This is difficult to say. Sipunculans, as many other non-polychaete ‘worms’, are lacking many anatomical characters to split species. We can say sipunculans are quite cryptic species by the simplicity of their anatomy. Just soft invertebrates without parapodia, nor chaeta. On the other hand, we should admit the existence of large areas in the oceans not well sampled, which could give further new taxa. By forcing us to estimate numbers: I would say from 10 to 25 species still undiscovered based on classical methods in identification (dissection + microscope). Based on this classical method, the rate of new species would remain strikingly low.</p> <p>Cryptic However, by using DNA analysis, some species (‘= cosmopolits’ + eurybaths + circumtropical + or present in several oceans at the same time) could be splitted into several new clades. There are about 30–50 species with very wide horizontal + vertical distribution. If we assume a range of 2–5 clades as average, we can guess around 60–250 new clades by molecular methods. From this range: 60–250 minus 30–50 = 30–200 additional species by using genetics.</p> <p>Note that Kawauchi & Giribet (2010) published on a single species of Sipuncula, in which they identified 4 cryptic species with wide distribution.</p> <p>References Kawauchi, G.Y., and Giribet, G. (2010). Are there true cosmopolitan sipunculan worms? A genetic variation study within <i>Phascolosoma perlucens</i> (Sipuncula, Phascolosomatidae). <i>Mar Biol</i> 157, 1417–1431.</p>
Tardigrada [Reinhardt Møbjerg Kristensen]	<p>Described There are 973 species of tardigrades of which only 183 species (and subspecies) are marine, however on genus level the marine tardigrades are more diverse than the terrestrial/limnic tardigrades. Arthrotardigrada are all marine except for one species, <i>Styraconyx hallasi</i> — which is found in a salt spring in Westgreenland. There are 5 families in Arthrotardigrada. I have 158 accepted species; some of them were described as subspecies. Echiniscoidea are most terrestrial — however 1 family is tidal/marine. 18 species have been described. Eutardigrada are all terrestrial/limnic except for one genus, <i>Halobiotus</i> which contains 6 species. Furthermore one species of <i>Isohypsibius</i> has been recorded from a marine beach! I know two more species of <i>Halobiotus</i>.</p> <p>Undescribed/undiscovered We know about 500 undescribed Arthrotardigrada species — I estimate about 1,000 undescribed Arthrotardigrada will exist. I estimate the family Echiniscoididae has about 100 undescribed species, we already know 20 undescribed species of the genus <i>Echiniscoides</i> and I will not expect more than 20 undescribed species of Eutardigrada.</p>

<p>Acoela [Tom Artois, Seth Tyler]</p>	<p>Described 391 species.</p> <p>Nominal 605 species names.</p> <p>Undescribed, collected 100 species.</p> <p>Undiscovered 4,000 species. Same rationale as for the Rhabditophora.</p> <p>[Seth] I fully concur with Tom and Marco. I expect similar estimates could be applied to the Acoela, but with them, the number of ecoregions sampled is probably far fewer than 81 — on the order of 20, I would guess; and again, except for those famous regions such as the Baltic, North Sea, Western Mediterranean, and Southeastern Brazil, the sampling has been haphazard at best. So the number of undiscovered species may be even proportionally higher in Acoela than Rhabditophora, but I am not prepared to hazard a guess.</p> <p>Cryptic We haven't seen any evidence for cryptic species in the acoels; in fact, we've seen evidence to the contrary (Matthew Hooge, pers comm.). We would suspect that cosmopolitan species (<i>e.g.</i>, <i>Childia groenlandica</i>), and those found over a wide geographical area (<i>e.g.</i>, <i>Hofstenia miamia</i>) might actually be species complexes, [but] molecular studies have supported the monophyly of these species. It also seems relevant to note that the acoel species usually have limited geographic distribution.</p>
<p>Nemertodermatida [Tom Artois, Wolfgang Sterrer]</p>	<p>Described 8 species.</p> <p>Nominal 10 species names.</p> <p>Undescribed, collected See undiscovered.</p> <p>Undiscovered As to the Nemertodermatida, I think the number of undiscovered species is much higher than 10. In a recent sampling campaign with Ulf Jondelius in North Sardinia (only 8 days), Ulf found 5 species of Nemertodermatida, 4 of which he thinks(!) are new to science. To have certainty about that, molecular data should back this up, and this research has just been started. The number of undiscovered species is difficult to estimate. These species are extremely difficult to distinguish morphologically. Molecular techniques probably will reveal a much larger biodiversity, which I think is kind of illustrated by this recent sampling campaign with Ulf. That's why we propose to keep the number of undescribed and undiscovered species for Nemertodermatida in the table with a question mark.</p>
<p>Xenoturbellida [Serge Gofas]</p>	<p>Xenoturbellida is now part of the new phylum Xenacoelomorpha.</p>

	<p>There are only two species in this group. For a taxon with such a low number, it is not reasonable to venture a guess about undescribed/undiscovered species.</p>
